Conclusion

This entry delves into the use of motion matching techniques in character animation systems for video games. It presents a mathematical description of motion matching, the main components of a motion matching-based animation system, and practical guidelines followed by industry practitioners.

Motion matching synthesizes responsive, smooth motion by selecting the most appropriate animation subsequence for the current game situation and blending it with the currently playing animation. The construction of the query space, a retrieval space that separates potential starting points of animation subsequences through featurization at each frame, is a key element of the algorithm. By comparing recorded frame features with features constructed at runtime, it is possible to find the closest frame of animation from which to start blending. Forming queries that match the data and the prepared query space is crucial to achieve satisfactory motion smoothness and responsiveness.

Those interested in learning more about motion matching techniques can refer to (Bergamin 2021) for a thorough mathematical definition, (Häfliger and Kurabayashi 2022) and (Holden et al. 2020) for implementation details, and (Holden 2021a) for a standalone open-source implementation.

Motion Planning in Computer Games

Amol D. Mali
Computer Science Department, University of Wisconsin-Milwaukee, Milwaukee, WI, USA

Introduction

Planning motions of characters is necessary in some computer games because of several reasons. Positions of existing obstacles or opponents change, making predefined paths unsuitable.

New obstacles may be introduced in the gaming environment unpredictably, making motion planning necessary. Position of goal, like the treasure to be seized, may change unpredictably, making motion planning indispensable. Even if it is possible to predefine paths that are guaranteed to remain collision-free in some games, motion planning is needed to synthesize diverse paths to avoid predictability and unnatural motion. Some games have too many moving characters to predefine paths for, and motion planning is important for them even if they are nonplaying characters because they enhance player experience. Even if there are very few moving characters, there may be too many combinations of motion constraints to be satisfied at different times, making precomputation of motion plans infeasible. Other reasons for motion planning include expansion of the gaming environment enabled by portals, different speeds of characters, and multiple locomotion modes of characters. In some computer games, the challenge lies in deciding where to move next and not how to move there. In some computer games, the challenge lies in finding how to move to goal and not selecting goal. Some of the references in this article do not describe a computer game, but some ideas in them are usable in computer games. The emphasis of this article is on representative heuristics, strategies, tactics, challenges, geometric and logical representations, types of constraints to be satisfied, and evaluation metrics in motion planning in computer games and not on physics of motion and algorithmic details.

Terminology

Degrees of freedom: The number of degrees of freedom (DOFs) of a moving agent is the minimum number of parameters whose values need to be specified to completely specify the position and orientation of each part of the agent with respect to a fixed coordinate system.

Desirability map: It shows the desirability of visiting individual locations in a gaming world. The desirability is usually computed by combining the values of attributes related to direct or indirect or delayed or immediate reward and punishment.

Navigation mesh: A navigation mesh is obtained by partitioning the free space into convex polygons or polyhedrons, commonly referred to as *cells*. A collision-free path can then be found by searching a graph capturing connectivity of these cells and joining subpaths contained in these cells.

Roadmap: In the context of motion planning, a roadmap is a graph such that each of its vertices is a configuration of a moving agent like a point robot and each edge represents transition from one configuration to another through movement. If a roadmap is connected and is stored for future use, a path from an initial configuration to goal configuration can be found by connecting each of them to some vertex in the roadmap, instead of finding from scratch.

Waypoints: They are points between start and goal configurations used to guide an agent's navigation.

Voronoi diagram: Given a two-dimensional shape and a set of n points called *seeds* or *sites*, its Voronoi diagram is a collection of points partitioning the shape into n regions such that all points in each region are at least as close to one seed as any other seed.

Generalized Voronoi diagram (GVD): Given a shape S with shapes inside it, like a polygonal boundary with polygons within it, the GVD of S is the collection of points such that each of these points is equidistant from at least two shapes in S closest to it.

Medial axis: The medial axis of a shape is the set of centers of largest balls that can fit inside the shape such that each ball meets the boundary of the shape only tangentially at least two points. The medial axis changes if the object is deformed.

Motion clip: It is a short video containing motion of one or more objects.

Motion graph: A vertex of a motion graph is a motion clip or component of a motion clip. An edge of this graph represents that a transition from one clip to another is possible, making compound motion possible by joining motion clips connected by the edge. The graph can have cycles.

Motion database: A motion database used for computer animation contains motion clips.

Inverse kinematics: It is a process which finds positions and orientations of parts of a moving agent which ensure that a specific subsystem of the agent (usually the end effector like a gripper) is in the desired configuration.

Sampling-based motion planning: It is a paradigm which involves creating samples (geometric configurations) of the moving agent, randomly or with a bias, and connecting them to create a roadmap which is used for finding a collision-free path.

Motion Planning for One Agent

Motion planning for one agent is relevant when there is only one moving agent or there are multiple agents that move fully independent of each other without having to worry about collisions among them, but collisions with nonmoving objects are to be avoided. Kovar and others (Kovar et al. 2002) introduced motion graphs for efficient composition of motions to create compound motions. Rahim and others (Rahim et al. 2009) report on creation of motions for animated characters using motion graphs derived from motion clips from a motion database. These motion clips contain running, walking, jumping, and other types of movement. They review distance metrics used to find similar poses in clips to find transitions possible between motion clips or their components, to establish the edges of a motion graph. The virtual agent in (Rashidian et al. 2014) has to visit at least one goal from each of the k groups of goals, starting from the given initial configuration in presence of static obstacles. This is referred to as *multigroup motion planning* in (Rashidian et al. 2014). Their approach includes finding a tour for the virtual agent without considering obstacles and using sampling-based motion planning to consider obstacles. Their experiments included a ground vehicle and an aerial vehicle. The digital mannequin in (Arechavaleta et al. 2004) has 53 degrees of freedom. It is composed of 20 rigid bodies connected by 18 joints. The object carried by the mannequin has 6 degrees of freedom. Since it is extremely hard to find a collision-free path for a system with 59 degrees of freedom, the system is first treated as a 9-DOF system by constraining the configurations of the mannequin and the object. Once a collision-free path is found, the frozen parts of the system are animated in a collision-free manner to create a natural motion.

The path planning approach in (Juarez-Perez and Kallmann 2018) associates a clearance, preference, and cost with each behavior. They consider three behaviors – (i) frontal walking, (ii) constrained frontal walking, and (iii) lateral walking or sidestepping. Arms are relaxed during frontal walking, but this behavior needs higher torso clearance. Frontal walking is the most preferred behavior and costs the least. Constrained frontal walking needs lower torso clearance, costs more, and is less preferred. Lateral walking is the least preferred behavior among the three, costs the most, but needs the least clearance, making it indispensable for navigation through narrow passages. For efficiency, their approach doesn't check for collisions between certain obstacles (like short obstacles) and torso of the moving character since such collisions are impossible. Their layered approach initially finds a collision-free path using the costliest behavior (sidestepping) which is also the least preferred behavior and needs the least clearance. The layered approach then tries to reduce the path cost by improving the initial path using more preferred behaviors which also cost less and need higher clearance. The path planning approach in (Kapadia et al. 2013) handles hard and soft constraints. Each soft constraint has a weight showing how important its satisfaction is. Satisfaction of hard constraints is mandatory. Satisfaction of soft constraints is optional. Some of the nodes and edges in their hybrid state-transition graph are obtained by partitioning the free space into triangles in a specific way. Some nodes and edges in this graph are obtained by laying a uniform grid over the free space such that a node in the grid has up to eight neighbors. Some nodes and edges in this graph are obtained by laying triangles over the free space for

representing spatial relations satisfying spatial constraints on a path. Examples of spatial relations include an agent being on the right or left of an object or in the line of sight of a patrolling guard. Nodes and edges added to the hybrid state-transition graph because of triangular cells and their adjacency allow faster synthesis of paths and reduction in path length. Nodes and edges added to the graph by uniform grid allow synthesis of paths satisfying diverse constraints.

It is pointed out in (Lee et al. 2006) that capturing motion data in a physical environment and adapting it to a virtual environment is a bottleneck in computer animation. This is because creating or renting complex/specialized physical environments and having humans perform various actions in them and creating digital approximations of real environments and real characters can be time-consuming and pricey. They propose a data-intensive scalable approach in which a complex virtual environment is composed of small units and the motions in this environment are composed of the motions associated with these small units, e.g., a large playground can be created by populating it with curved slides and straight slides, and complex motion in this environment can be composed of walking, climbing, and sliding motions. A *building block* (also known as a *motion patch*) in their work consists of an environment-building unit like a curved slide and specific motions available with it. Motions available in an environment-building unit are reusable in a copy of it. Their approach is usable for multiple agents too. They report that an office environment can be generated using a desk-chair combo and square ground panel. The motion patches for an office environment they identified based on 40 minutes of motion are (i) sitting down or standing up, (ii) working at a desk, (iii) chatting at a desk, (iv) standing idle at a place away from all desks, (v) chatting at a place away from all desks, (vi) disputing at a place away from all desks, (vii) making a presentation while standing away from all desks, and (viii) walking and then stopping. Instead of generating an environment with obstacles and then finding collision-free paths in it, the approach in (Lee et al. 2006) offers a combo of an environment and collision-free motion, significantly reducing or eliminating the computational complexity of motion planning because motion planning is then needed only for characters or environment not based on motion clips. It is possible to compose character motions and then include nonmoving objects in a manner that avoids motion conflicts.

Motion Planning for Adversaries

The motion planning approach suitable when there are adversaries depends on their count, separation distance possible, speeds, directions of movement, and other constraints like staying visible to nonplaying agents, if any. Park and others (Park et al. 1997) present a computer game containing two boxing robots such that one of them is controlled by the human player and the other is computer-controlled. The human player's arm movements are tracked with 3D position sensors attached to wrists and elbows. The motion planner for the computer-controlled boxer finds offensive motions to hit the human-controlled boxer and defensive motions to prevent being hit on its hittable surface. The motion planner samples the position of fist of the human-controlled boxer at a fixed frequency and uses it along with passage of fixed time without a punch from the human-controlled boxer to decide whether to be offensive or defensive. Hittable areas of each robot are two predefined rectangles which are discretized assuming that there are finite hit points. Blocking a punch with a forearm is the only defense strategy. The motion planner computes the ratio of the distance from the defending forearm of the human-controlled boxer and the distance from the hitting fist of the robot-controlled boxer for individual exposed hittable points on the human-controlled boxer and targets the point with highest ratio during offense. Inverse kinematics is used for motion planning.

Shamgah and others (Shamgah et al. 2016) present an abstract model in which the attacking robot tries to move to reach its target cell in a grid with the defending robot trying to move to capture

the attacking robot. The number of strategies for each player in this reach-avoid game is the number of cells it can move to next. The payoff for the defender for strategy combination (i,j) is $e(a_i, t)/e(a_i, d_j)$ where function e is the Euclidean distance between its arguments, a_i is the cell in which the attacker will end up by following strategy i (same as moving to cell i), t is the target cell the attacker is trying to reach, and d_j is the cell in which the defender will end up by following strategy j (same as moving to cell j). The attacker wants to move to minimize this payoff. The defender wants to move to maximize this payoff. This model can be realized in computer games in multiple ways, e.g., having one attacker and one defendant with multiple target cells that vanish if not reached in cell-dependent time, having multiple attackers and one defendant, having one attacker and multiple defendants, and allowing an attacker to be captured a certain number of times. Instead of generating the payoff matrix with all strategy combinations to guide the movement of computer-controlled characters, a partial payoff matrix with randomly chosen strategy combinations can be used. This will not only be computationally efficient, but it will also often result in suboptimal choices for computer-controlled characters which will make them more believable and boost the morale of the human player by increasing his/her chance of winning.

Motion Planning for Crowds

Li and others (Li et al. 2017) present an implemented and evaluated hybrid approach to model motions of agents in a crowd. In an agent-based approach to crowd simulation, each agent is autonomous. In cellular-automaton approach to crowd simulation, agents have no autonomy at all. In the hybrid approach in (Li et al. 2017), each agent is autonomous and has a positive tolerance value which is the number of time steps for which it can wait in its current cell before moving to the next cell. When multiple agents want to move to the same cell, the agent which waited the longest in its current cell has the highest probability of moving to the cell. The crowd simulation model in (Liu and Chen 2008) allows different types of agents. Their implementation has many birds, deer, and tigers. Besides having different speed and acceleration, they exhibit different behaviors. Birds fly or rest. Deer wander, march toward goal, or evade tigers. Tigers wander, trace deer, and attack. There is a finite-state machine (FSM) for each kind of animal. The FSMs specify conditions for transition between behaviors.

The main objective of the crowd simulation approach in (Chang and Li 2008) is maintaining the shape of the crowd, e.g., a square or convex nonagon. Opposing troops in a battle can form different shapes. Their approach first generates a path for the shape representing the crowd. If needed, the shape is deformed to avoid obstacles. Individual agents exhibit different behaviors within the shape, e.g., changing or maintaining speed or orientation or staying still. A gamified approach to crowdsourced design of floor plans is presented in (Chakraborty et al. 2017). Human players don't plan motions of characters. They design floor plans by choosing the locations and numbers of doorways, walls, and pillars, starting with the layout provided by an architect or designer. A player can change density of crowd and distribution of agent speed, acceleration, and agent width and height. After designing the floor plan, a human player can run simulation which ends after evacuation of the environment is complete. Players are ranked based on evacuation time. This work can be viewed as a way to verify that motion planning and execution meeting certain constraints is possible in the given environment. By running simulations with different parameters, one can find how motion-friendly an environment is. Some approaches to crowd simulation involve guiding the moving characters along medial axis or the edges of a Voronoi diagram or a GVD or some other type of roadmap. Though this can result in slow movement of characters due to waiting and make motion look unnatural and predictable, it makes collision avoidance easier. The approach in (Oliva and Pelechano 2013) dynamically generates waypoints for characters with different radii to avoid these problems.

Conclusion

Motion planning in computer games has used some of the advances in robot motion planning, computational geometry, computer animation, and search in artificial intelligence. Still, high computational complexity associated with large state spaces and loss of completeness and optimality typically associated with scalable motion planning techniques is inherited by computer games using these techniques. There is scope for research on modifying techniques and representations used in robot motion planning and search in artificial intelligence, using the freedom to include fiction in computer games.

The art of electroencephalography

Definitions

Electroencephalography, or **EEG**, is an electrophysiological monitoring device comprised of multiple electrodes (small, flat, metal discs with thin wires) placed on the scalp that send signals to a computer in order to noninvasively measure and record electrical activity on the scalp. **EEG** can be used in cognitive research or to diagnose conditions such as epilepsy and sleep disorders.

Biofeedback systems are computerized devices that provide information about the activity of physiological measures, such as heart rate variability, in order to learn how to modulate at will specific body functions to improve energy management, health, self-mastery, and general well-being. Biofeedback systems may include EMG machines, ECG, heart rate variability, respiration, and EEG among others.

Heart rate variability (HRV) is a measure of the patterns prescribed by inter-beat intervals of time and the functioning of the heart. **HRV** has been described as a psychophysiological biomarker to assess coherent or stressful states associated with respiration, cognition, and emotions (McCraty et al. 2009).

Psychophysiological coherence has been widely described as a state conducive to optimal cognitive performance, improved health and also associated to inner balance, peace, and harmony (McCraty et al. 2009).

Introduction

This entry describes the development and use of the art of movie-making in order to display spatiotemporal dynamics in complex systems such as brains. This qualitative tool has been used in visualizing, analyzing, and understanding brain dynamics as a new form of the art of encephalography (Davis et al. 2015; Davis and Kozma 2013). This tool has also been applied in order to visualize individual heart rate variability (HRV) in group dynamics in the study of psychophysiological coherence and its relationship to inner peace and social harmony (Davis et al. 2018; Heart Coherence Ratio per Participant 2018). It would be possible, in principle, to apply this method to study any complex system that can be described as an array of signals that comprises a region of a system, which can be described as a whole in itself, for example, regions of the visual cortex.

This comes as a new and more advanced way to display images with the purpose of visual discrimination associated with the different brain cognitive states or heart coherent states, for example, in order to better understand and formulate theories of different stages of cognitive processes related to the creation of knowledge and meaning, intentional action, and value-based decision making (Davis and Kozma 2013; Davis et al. 2015a; Kozma and Davis 2018). The movies allow us to visualize different patterns of behavior in different conditions produced by different stimuli based on experimental data. By careful observation of each of these movies, the researcher learns to identify different structures and visual patterns where, for example, large-scale synchronizations and desynchronizations can be observed across different frequency bands (Davis et al. 2013; Myers et al. 2014).

Overview of the Methodology

A thorough description of this methodology, particularly applied to brain data, has been presented in previous work (Davis et al. 2015) together with an introduction to the different costs and benefits associated to it in terms of time consumption (hours

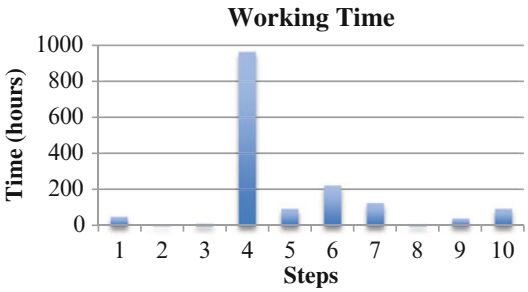
of work). Generally speaking, in order to more efficiently produce a greater amount of movies from brain data, for example, the more man and computer power is required. However, with a fair amount of people, like a team of two (2), and two (2) relatively powerful laptops, a considerable amount of movies can be made. It is important to note that in "The Art of Encephalography to Understand and Discriminate Higher Cognitive Functions Visualizing Big Data Imaging Using Brain Dynamics Movies" (Davis et al. 2015), 39 experiments (runs) in 4 bands for 4 indices (signals), for a total of 624 individual movies, were produced for a total work time of around 1623 h, which equates to around 10 or 5 months (1623 h) with 1 or 2 fulltime analysts, respectively, each working 5 days a week for 8 h a day. To illustrate this, it is important to note that the methodology is comprised of ten (10) steps as follows:

Step 1: Signal preprocessing and movie generation (~52 h)
Step 2: Movie downloads to computer (~4 h)
Step 3: Organization and editing of projects (~13.3 h)
Step 4: Synchronization of different runs or experiments into one movie that displays them all at the same time (~960 h)
Step 5: Corrections and art editing (~96 h)
Step 6: Rendering and further editing (~224 h)
Step 7: Exporting edited movie (~128 h)
Step 8: Finalizing corrections and speed calibration (~8 h)
Step 9: Final rendering (~42 h)
Step 10: Exporting and publishing final movie to website (~96 h)

The distribution of the workload across all steps is presented in Graph 1. Note that, Step 4 together with Step 6 are the major time-consuming activities requiring manpower skills, and therefore, in order to cut that time, more people, computers, software, and working space are needed.

Movie-Making and the Art of Encephalography via EEG Measurements

These movies allow researchers to explore the temporal evolution of spatial patterns where they can identify, in the case of brain dynamics, the different stages in the manifestation of, for example, a hypothesized cycle of creation of knowledge and meaning. These types of studies have been conducted both in animals and humans to capture brain dynamics in response to salient stimuli (Davis and Kozma 2012; Kozma et al. 2012), as well as the study of brain dynamics in different cognitive states (Davis et al. 2016; Davis et al. 2017).



Movie-Making of Spatiotemporal Dynamics in Complex Systems, Graph 1 Working time per step in the movie-making methodology

Movie-Watching and Pattern Recognition

It is conjectured that movie viewing will allow a better understanding of learning, adaptation, and cognition in general, by allowing researchers to familiarize themselves with very distinct patterns of the behavior of a complex system, like, for example, group coherence and synchronization between individuals in different group activities (McCraty 2017; McCraty et al. 2017; Timofejeva et al. 2017). In the case of cognition and consciousness, many of the philosophical implications associated with intentional behavior and value-based decision-making that have been published (Davis et al. 2015a; Davis et al. 2017; Kozma and Davis 2018) highlighted the value of using brain dynamics movies in the uncovering of different cognitive states and the cycle of creation of knowledge and meaning.

Further Comments on the Art of Encephalography

In summary, it can be said that viewing brain dynamics movies will allow a significant impression of brain events for different measurements, brain events across bands and the different stages

of the cycle of creation of knowledge and meaning, as well as the design of better monitors and biofeedback systems that will have to meet the challenge of efficiently processing large amounts of data online. With that in mind, many researchers interested in the study of consciousness and cognition, for example, will be able to discuss their insights after watching brain dynamics movies in a set of iterative brainstorming sessions. One can imagine and be positive that this kind of activity and approach will allow the emergence of better theories about brain functions, cognition, and consciousness in general. It is important to note that this way of visualizing brain dynamics has been inspired by the work of Walter J. Freeman who was a great pioneer and luminary of systems neuroscience.

Methodology and Applications

Usually complex systems are represented as a set of signals or time series which share a certain correlational or causal structure, and when viewed independently as a collection of plots over the same time axes, a substantial amount of information related to the spatial configurations and patterns that arise in each moment or time step (t) is lost. In order to capture the spatiotemporal dynamics, the need arises to display the signals, $x_i(t)$ with $i = 1,2,\ldots N^2$ in a new configuration, as follows:

$$X_{ij}(t) = \begin{pmatrix} x_1(t) & x_2(t)\ldots x_N(t) \\ x_{N+1}(t) & x_{N+2}(t)\ldots x_{2N}(t) \\ x_{2N+1}(t) & x_{2N+2}(t)\ldots x_{3N}(t) \\ \vdots & \vdots \\ x_{7N+1}(t) & x_{7N+2}(t)\ldots x_{N^2}(t) \end{pmatrix}_{NxN}$$

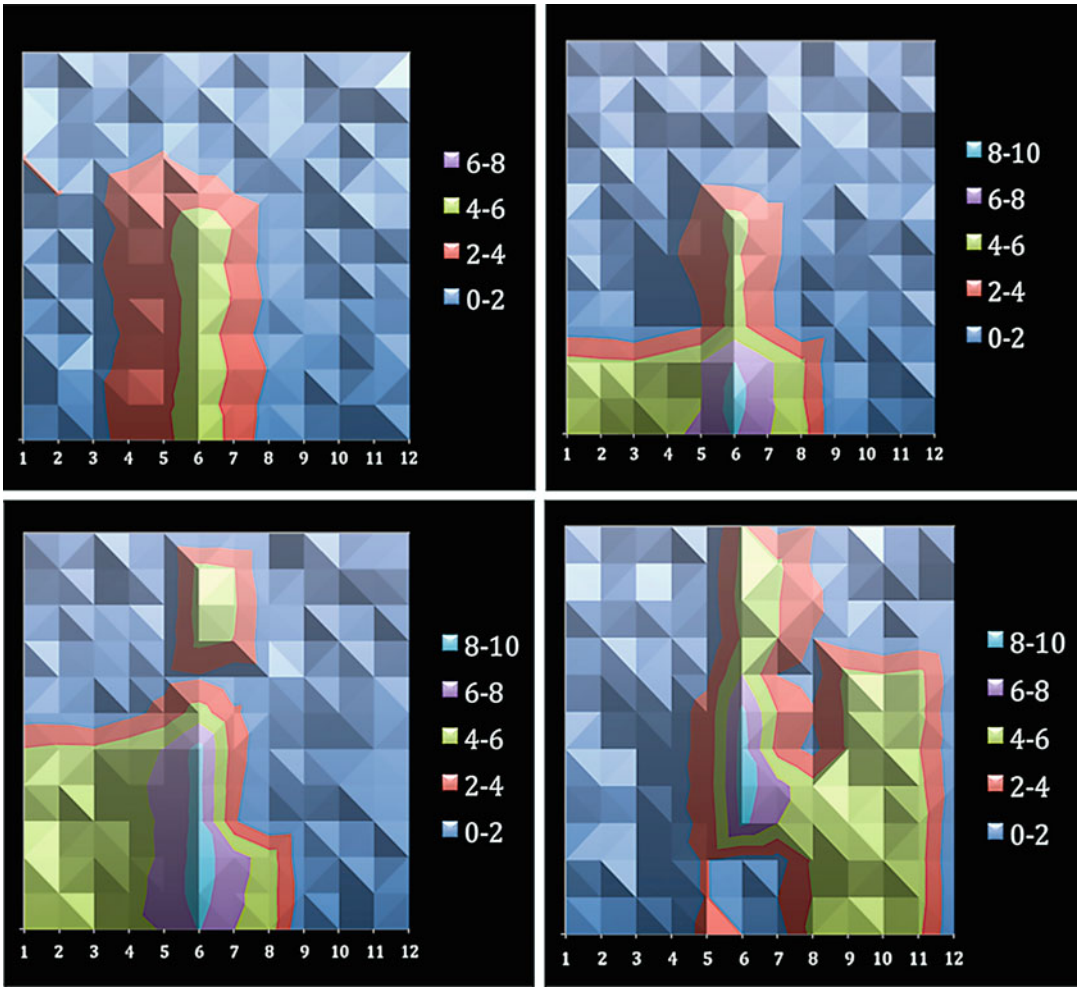
or

$$X_{ij}(t) = \begin{pmatrix} X_{11}(t) & X_{12}(t)\ldots X_{1N}(t) \\ X_{21}(t) & X_{22}(t)\ldots X_{2N}(t) \\ X_{31}(t) & X_{32}(t)\ldots X_{3N}(t) \\ \vdots & \vdots \\ X_{N1}(t) & X_{N2}(t)\ldots X_{NN}(t) \end{pmatrix}$$ for every time step t.

One can imagine every element of this matrix to be a pixel or a point to be displayed in a surface plot. If one assigns a color to each point and displays the surface in each time step (t), then the color patterns may reveal an orderly movement. When this set of surface plots is captured as frames of a movie and they are played at a certain speed, then the emergence of a spatiotemporal pattern may be observed. An example could be a simulated set of signals that could represent electrodes implanted on the cortex of an epileptic patient, in order to measure brain activity via ECoG. The following fictional example portrays a square array of 12×12 as if it was placed on the cortex of a patient with epilepsy, similar to the ones described in recent studies (Heck et al. 2016). The simulated patterns that emerge could look like the following sequence of surface plots in different moments of simulated data plotting amplitude values in the range of [0,10], as in Fig. 1.

Similar to the above simulated signals, recent studies using this methodology have shown that spatiotemporal brain dynamics could be tracked in terms of amplitude modulation patterns that could reveal responses to stimuli (Davis and Kozma 2013; Davis et al. 2013). This same methodology could be applied to brain dynamics measured on the scalp of a human, where the electrodes are placed all over the scalp and their associated signals are displayed for each point in the matrix, in each time step (t). In recent studies, the dominant frequency band (theta, alpha, beta, or gamma) has been studied under different cognitive modalities and these kinds of movies were used to track changes in the dominant frequency band (representing brain dynamics) for each part of the cortex (Davis et al. 2016, 2017). Figure 2 depicts two (2) moments where the change in the dominant frequency band can easily be appreciated for the arrangement of electrodes placed on the scalp that were obtained in the study just cited before (Davis et al. 2017). The displays show a spatiotemporal landscape related to one participant, in one particular time, in one particular modality (EEG Dunedin Movies 2018).

Similar movies can be developed based on studies of group dynamics using the heart rate



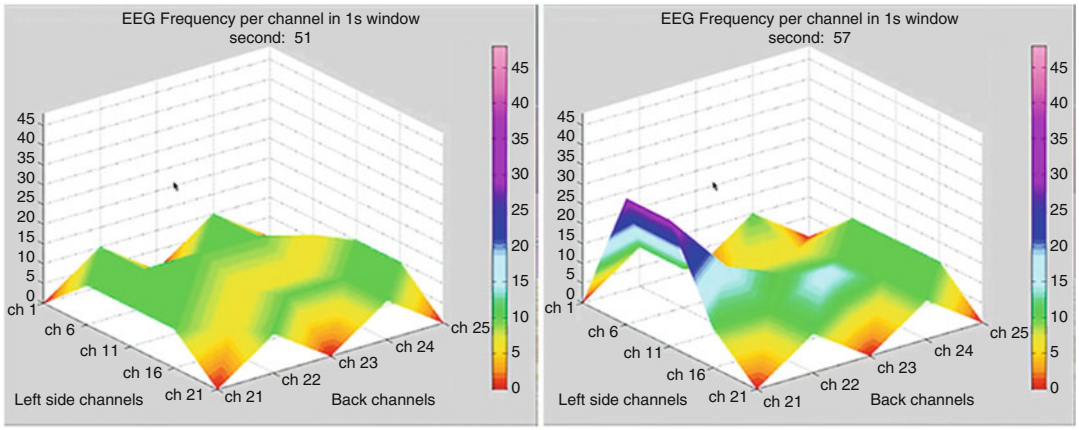
Movie-Making of Spatiotemporal Dynamics in Complex Systems, Fig. 1 Simulated signal amplitudes (144) placed in an imaginary 12×12 array showing 4 different consecutive times and the evolution of the system for t = 0 (top left), t = 1 (top right), t = 2 (bottom left) and t = 3 (bottom right)

variability (HRV) or a coherence ratio measure of each participant as the signal to be displayed in each time step (t), showing a group spatiotemporal landscape as shown in (Davis et al. 2018; Heart Coherence Ratio per Participant 2018) (Fig. 3).

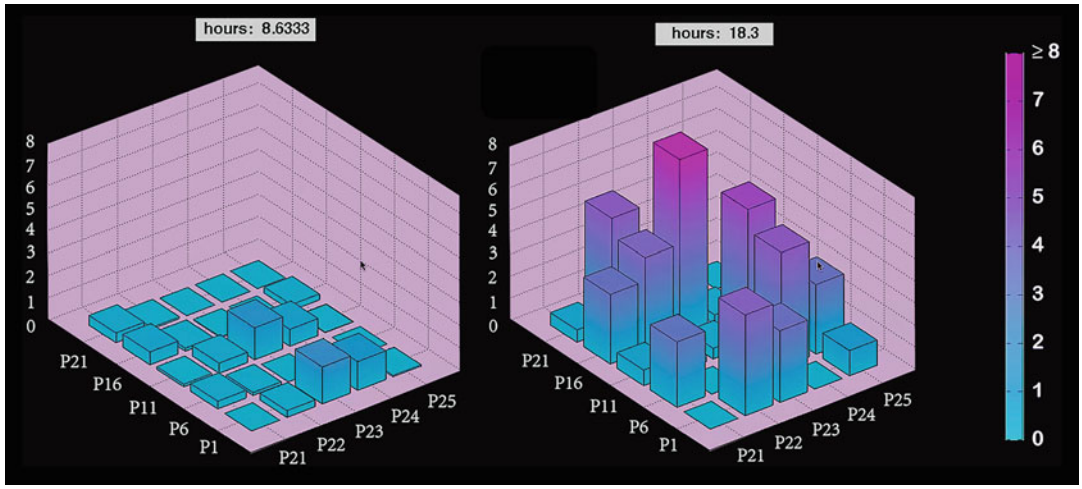
It is important to note that these kinds of studies with the aid of complex systems movies, like brain dynamics movies, could assist in the understanding of consciousness associated to different cognitive states, as in meditation and relaxation, or energy-consuming activities like reading difficult material, revealing different patterns in both brain and HRV dynamics (Davis et al. 2017; Davis and Kozma 2018). Studies conducted in recent years using this methodology have shown that brain dynamics associated with intentional behavior have their foundation and are deeply rooted in the creation of knowledge and meaning that takes place in mind-brain dynamics (Davis et al. 2015a; Davis 2018; Kozma and Davis 2018).

Conclusions and Future Perspectives

A methodology has been presented for displaying signals related to complex systems like brains and



Movie-Making of Spatiotemporal Dynamics in Complex Systems, Fig. 2 Displays of the dominant frequency band for 19 electrodes that cover the scalp and are arranged in a 5×5 array where six (6) dummy electrodes are anchored in zero (red), showing two (2) different moments in the evolution of human brain dynamics for t = 51 s (left) and t = 57 s (right)



Movie-Making of Spatiotemporal Dynamics in Complex Systems, Fig. 3 Display of the HRV coherence ratio for twenty two (22) participants in two (2) different activities over an array of 5×5 where three (3) positions (23, 24 and 25) are left in zero (0). **Left:** Baseline activity around 8:36 a.m. (low group coherence) and **Right:** A group meditation activity around 6:20 p.m. (high group coherence)

communities among others, where the displays are turned into movies based on sequential frames, where the evolution and dynamics of the system can be qualitatively studied in space and time. The challenges associated with the production of these movies are various, requiring efficient big-data processing algorithms and computer technologies that minimize the latencies between frame displays. This will ideally allow good quality movies, very close to online times biofeedback system displays. These kinds of new technologies could facilitate an efficient and comfortable qualitative interaction between computers and humans through brain-computer interfaces, where humans can presumably learn to modulate their own internal cognitive and psychophysiological states and in so doing, minimize stress and improve well-being. The use of this

methodology can be foreseen in the study of cognition and consciousness by increasing the experimental database that is derived from EEG measurements on the scalp of human participants under different modalities presumably leading to different cognitive states. It also can be conjectured that with a careful visual and statistical analysis (qualitative and quantitative), researchers will be able to uncover the intrinsic relationship between signals associated to respiration and brain-heart dynamics. It has been shown that human beings can generate psychophysiological states which are reflected in HRV and that are conducive to cognitive clarity and stress reduction (Heck et al. 2017). It is likely that in the future, the use of this methodology in the implementation of biofeedback systems will assist human beings in the mastery of inner peace, general well-being, and social harmony, where ideally one will be able to self-monitor heart-brain-respiration and other physiological signals almost in online time (minimal latency) and all signals at the same time.

Definition

Multi-user virtual environments (MUVEs) are structured with three-dimensional objects, in which users can actively navigate their avatars to different areas of the immersive environment.

OpenSimulator (OpenSim) is an open source multi-platform and multi-user 3D application server.

Introduction

Online multi-user virtual worlds have been used since the late 1970s (Achterbosch et al. 2007; Shield 2003). Initially, these environments were text-based interaction called multi-user dungeons (MUDs). With the transformation of MUDs to MOOs (MUD, object-oriented), users started to modify these worlds (Tüzün 2006). Advances in information and communication technologies have driven the MOOs' evolution, resulting in diverse human computer interfaces such as multi-user virtual environments (MUVEs) and massively-multiplayer online role-playing games (MMORPGs) (Dieterle and Clarke 2009). Newer generations of these environments are called immersive virtual worlds or metaverses (Dalgarno and Lee 2010). All of these virtual worlds are displayed online in three-dimensions (3D), and users can move and interact in simulated 3D spaces (Dickey 2005) that can be changed and modified. Users are represented as modifiable 3D avatars that can interact with other 3D avatars and do many activities such as walking, flying, running, jumping, and dancing. Avatars can be designed based on a user's real-life appearance or imaginary appearance (Fig. 1).

Three-dimensional multi-user virtual environments (3D MUVEs) can be used for different purposes such as socializing, entertainment, education, or business. A number of opportunities offered by 3D online virtual environments compared to 2D equivalents have led to great expectations, especially in the field of education. Using 3D MUVEs for education has the potential to create a constructivist learning environment where learners' interactions and communications using avatar-to-avatar activities can challenge them to figure things out for themselves (Educause 2006). Social organizations formed in 3D virtual microenvironments might make a significant contribution to learners' self-perception and moral values in the light of personal and social values. In this respect, 3D MUVEs seem to be well suited not only for cognitive and psychomotor learning areas but also for supporting affective learning (Barab et al. 2005; Bers 2001). Spatial knowledge representation provided by 3D MUVEs contributes to designing authentic learning environments, creating opportunities for experiential learning or learning contexts, and providing a rich learning experience that includes more effective collaboration and increases students' participation and motivation (Dalgarno and Lee 2010). In addition, students are encouraged to exhibit active involvement and learn by experience using applied activities (Coffman and Klinger 2008). 3D MUVEs contain teaching and learning activities such as problem-based

Multi-user Virtual Environments for Education, Fig. 1 Avatar examples for 3D MUVEs

learning, inquiry-based learning, game-based learning, role-playing, virtual quests, collaborative simulations, collaborative construction, design courses, language teaching and learning, virtual laboratories, virtual fieldwork, and attending classes (Duncan et al. 2012).

These environments' educational potential is summarized as follows (Kluge and Riley 2008; Freitas and Veletsianos 2010; González et al. 2013; Papachristos et al. 2014; Antonio et al. 2015; Dad et al. 2016):

- It reorganizes and extends social interactions and collaborations.
- It provides a free environment for learning.
- It supports active participation or "learning by doing" via authentic learning activities.
- It increases learner engagement, motivation, collaboration, and communication.
- It presents new opportunities and additional scope for creativity in learning such as role-playing and mentoring.
- It supports deeper learning by embedding simulations that are difficult to replicate in the real world including buying, selling, constructing buildings, dancing, clubbing, and even learning and training.
- It opens up new learning spaces and customized environments for rehearsal and exploration, experimentation and design, production, and user-generated content.
- It provides broader capabilities for learner-led activity as well as problem-based and exploratory learning.
- It provides learners with interaction via text, voice chat, or some animation movements.
- It offers remote access.
- It allows creation of a parallel world without limits to creativity and possibilities as the financial, spatial, and material constraints and the laws of physics are not applicable.

Three-Dimensional Multi-user Virtual Environments for Authentic Learning

3D MUVEs can be used for pedagogical classroom activities that are costly, complex, and even dangerous for learners and educators. 3D MUVEs offer opportunities to design authentic learning environments that focus on real-world complex problems and their solutions, using role-playing exercises, problem-based activities, case studies, and participating in virtual communities of practice

(Lombardi 2007). Herrington et al. (2002) identified ten characteristics of authentic learning environments:

- Authentic activities have real-world relevance.
- Authentic activities are ill-defined, requiring students to define the tasks and sub-tasks needed to complete the activity.
- Authentic activities comprise complex tasks to be investigated by students over a sustained period.
- Authentic activities provide the opportunity for students to examine the task from different perspectives, using a variety of resources.
- Authentic activities provide the opportunity to collaborate.
- Authentic activities provide the opportunity to reflect.
- Authentic activities can be integrated and applied across different subject areas and lead beyond domain-specific outcomes.
- Authentic activities are seamlessly integrated with assessment.
- Authentic activities create polished products valuable in their own right rather than as preparation for something else.
- Authentic activities allow competing solutions and diverse outcomes.

3D MUVEs represent a powerful media for instruction and have the ability to adapt to different learner needs (Mascitti et al. 2012). In addition, they can provide innovative ways to create challenging tasks in context (Iqbal et al. 2010). Thus, they can act as venues for authentic learning. Learners are part of a constructed environment and are engaging with the simulated environment, which is similar to real-life interactions (Farley 2016). There are some 3D MUVEs that allow designers and users to design a virtual environment such as Worlds.com (1994), Active Worlds (1995), Traveler (1996), Whyville (1999), Moove (2000), Second Life (2003), There (2003), IMVU (2004), Kaneva (2004), vSide (2006), OsGrid (2007), Smeet (2007), Smallworlds (2007), PlayStation Home (2008), Twinity (2008), Blue Mars (2009), and Onverse (2009) (Pearce et al. 2015; Tüzün and Özdinç 2016). Users utilize these environments for different purposes such as education, business, and entertainment. They may not always be appropriate for education because of user safety concerns, and authorization is limited to a user's land and avatar. In addition, there is a fee to customize some of these environments. In these cases, the open source platform called OpenSimulator can be used to create custom 3D MUVEs without fees or limitations.

OpenSimulator

OpenSimulator (OpenSim) written in C# is not a virtual world. It is an open source multi-platform, multi-user 3D application server to create your own virtual world (OpenSimulator 2017a) released under the BSD License. It provides the ability to customize and design virtual worlds for developers. OpenSim has features to support developers and users including:

- It runs on both a localhost and server using the Windows and Unix/Linux operating systems.
- It supports personal computers as a server.
- It supports online, multi-user 3D environments from one to thousands of simulators.
- It supports different sizes of 3D virtual spaces.
- Users access the same world at the same time.
- It supports real-time Physics Simulations.
- It supports users creating or modifying 3D content in real time.
- It supports using scripting including LSL (Linden Script Language)/OSSL and C#.
- It supports different database engines such as SQLite, MySQL, and MSSQL to store all content.
- It supports instant messaging by friends or groups.
- It supports loading different modules for configuration settings.
- It supports using external or internal VoIP services such as Freeswitch or Vivox.

The latest version of OpenSim was released on August 15, 2017 to users. However, some public distributors, such as diva distribution, add their own

modules and configurations and later share their repackaged OpenSim with users through the BSD license. It contains the standard OpenSim plus add-ons that support more features and tools that make the process of running and upgrading the virtual world easier (Diva 2013). Running in diva distribution is easier than OpenSim binary packages.

OpenSim can be started in stand-alone or grid mode. Stand-alone mode refers to operating all the data services in a single process when run as one or many regions. On the other hand, grid mode refers to using separate machines when multiple OpenSim instances run on different machines. Running in grid mode is more complicated than running in stand-alone mode (OpenSimulator 2017b). According to the number of users and intended use of the virtual worlds, the technical specifications for computers and servers will be different. For example, if a server is used for 20–25 users who perform tasks in virtual worlds, the following specifications will be sufficient:

- CPU: 4 Dual-core
- RAM: 8GB
- Bandwidth: If 20 users log in simultaneously, 10 MB/sec is necessary because each avatar or a user will use a minimum of 500 KB.
- Network Latency: Pings between the client and server should be better than 350 ms. It is important and critical on both upload and download to the simulator. It will affect avatar movement and object or avatar position changes.

If a server is used for 30–34 users who design in virtual worlds at the same time with VoIP, the technical specifications for the computers and servers must be improved. In addition, the number of objects used is a critical issue for these environments so storage capacity is important for designers. According to this example, the following specifications will be sufficient:

- CPU: 20 GHz
- RAM: 32 GB
- HDD: 300 GB SAS 10 K
- Bandwidth: Unlimited, 1000 Mbps Uplink

OpenSim provides an unlimited ability to customize virtual world applications easily with scene plug-in modules, although it is a highly complex system (OpenSimulator 2017c). Some of these plug-ins are for the startup of virtual worlds such as the region management plug-in. Other plug-ins are responsible for extending the functions of the virtual worlds such as voice or the effect of clouds and fog (Sun et al. 2010).

After the installation process, a viewer must be install as a user interface that allows users to modify or add connection settings to grids. The most popular of these viewers are Firestorm, Singularity, Cool VL, Kokua, Alchemy, and Radegast Metaverse Client (OpenSimulator 2017d). Most of these viewers are available for Windows, Linux, and MacOSX systems. A default avatar and an empty island will be displayed in the viewer in the first uploaded environment (Fig. 2).

After installation, OpenSim offers unlimited possibilities for users and designers based on their level. User powers are determined by User Level and Title (OpenSimulator 2017e).

- If a user's level is 0, the user is defined as default without any permissions.
- If a user's level is 1, the user may rename objects without modifying permissions.
- If a user's level is 100, the user may toggle character geometry, take copy, set to linden content, claim public land, and take ownership of an object.
- If a user's level is 150, the user can enable land auctions.
- If a user's level is 200 or 250, the user has full powers in the virtual world.

Initially, users' characters, called avatars, are displayed in the default view. However, they have an inventory and appearance options. Users can customize their avatars' shape, skin, hair, eyes, clothes, etc. and design their avatars' outfit.

OpenSim supports file formats and extensions as follows:

- Video: Flash (.swf), QuickTime (.mov), AVI (.avi), Mpeg (.mpeg), and RealNetworks Stream (.smil)
- Audio: MP3 (.mp3), WAV (.wav)
- Text: Text (.txt)

Multi-user Virtual Environments for Education, Fig. 2 OpenSimulator default context on viewer

- Image: Bitmap (.bmp), Jpeg (.jpeg), Mpeg (.mpg, .mpeg), Portable Networks Graphics (.png), Macintosh PICT (.pict), Silicon Graphics (.sgi), Graphics Interchange Format (.gif), Targa (.tga), and Tagged Image File Format (.tiff, .tif)
- 3D Model: Digital Asset Exchange (.dae), COLLADA (COLLAborative Design Activity), and Extensible Markup Language (.xml)
- Compressed files: Compressed TAR Archive file (.tgz), OpenSimulator Archive (OAR), and Inventory Archives (.iar)
- Animation: Biovision Hierarchy Animation File (.bvh, .anim)

3D objects are designed using basic objects called prims such as a cube or cylinder. Authorized users create prims, determine their position, scale, movement, and rotation, and combine them. Prims have different features:

- General: Object's name and description, owner, and permissions.
- Object: Object's x-y-z location, rotation, size, type, and physical features.
- Features: Object's light cast and flexible path.
- Texture: Textures can be 2D images or web contents on 3D objects.
- Content: All objects have the ability to store script or animation files.

Avatars interact with 3D objects and other avatars by touching them or script triggered behaviors. In addition, Head-Up Displays (HUDs) are useful objects for interaction. These objects can be attached to an avatar to create custom interfaces on a user's screen. Some interactions, messages, or textures can be added in the 2D view on HUDs.

OpenSim provides many opportunities for authentic learning utilizing customized virtual environments. The National Aeronautics and Space Administration (NASA) sponsored one of the largest projects with OpenSim, Virtual Missions, and Exoplanets (vMAX), between 2014 and 2017. vMAX developed a 3D virtual world using OpenSim to engage middle school students and educators. The overall project goal was to create a comprehensive NASA resource to engage students, educators, and the public in the search for worlds beyond Earth. In addition, it aimed to increase student engagement in STEM (Science, Technology, Engineering, and Mathematics), knowledge of exoplanet missions, and awareness of NASA-related careers (NASA n.d.). In this project, STEM includes astronomy and physics, technology such as telescopes and satellites, and

the engineering process and mathematics as applied to orbits and measurements. In addition, participants learn about exoplanets and related methods of detection as well as investigate via authentic learning activities using 3D MUVEs. Their avatars look like an astronaut and they complete tasks.

Conclusion and Discussion

3D immersive technologies, which initially came into daily life with modern computer games, have attracted research interest in the education field because of their pedagogical affordances such as enhanced learner engagement, motivation, and positive attitudes together with their openness to explore, design, and manipulate 3D objects. Today, there are increasing attempts to use 3D virtual learning environments in both face-to-face and distance learning settings to provide learners with more realistic and authentic learning environments.

OpenSim is an open source platform for building MUVEs. Unlike development platforms that offer ready-made services for accessing 3D spaces and 3D objects that can be used in these areas, OpenSim offers designers more manipulative design environments where all users can access the same design environment synchronously. Designers can also create 3D tools and objects that can be shared with other designers. Designers can modify shared 3D elements easily in accordance with their purposes. In addition, user security is high in OpenSim because of the use of private servers that are not accessible to everyone. It is important to know how to integrate pedagogy into these environments as well as how to use 3D environments created with OpenSim. However, the lack of guidance on how to organize instructional design elements and pedagogical arrangements in 3D MUVEs is a major limitation for educators.

Scatter chart; Scatter diagram; Scatter graph; Scattergram; Scatterplot

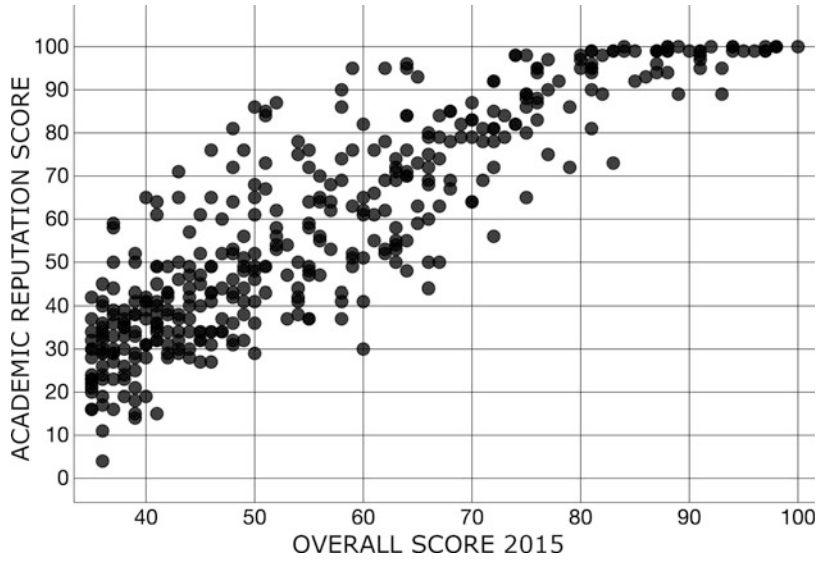
Definition

Multivariate visualization by scatterplots is the usage of diagrams to visualize sets of data that have more than three variables.

A scatterplot is a chart or mathematical diagram displaying a set of data as a collection of points using Cartesian coordinates, usually defined by horizontal and vertical axes. Each point on the chart represents two variables, x and y, calculated independently to form bivariate pairs (x_i, y_i). A functional relation between x and y is not necessary. The purpose of a scatterplot is to reveal (if existing) the relation between the displayed variables.

Introduction

Multivariate visualizations deal with the challenge of displaying sets of data with three or more variables: this peculiar feature poses two kinds of problems. First, most of the charts and diagrams usually adopted to visualize data cannot display more than three dimensions adequately.



Multivariate Visualization Using Scatterplots, Fig. 1 An example of scatterplot diagram

Second, the effectiveness of the visual effects adopted to represent different variables deteriorates when the number of variables increases.

Scatterplots may be considered, among the different types of data visual representations, as one of the most useful and versatile, especially in statistics. According to (Miller 1995), the term first appeared as Scatter Diagram in a 1906 article in *Biometrika*, "On the Relation Between the Symmetry of the Egg and the Symmetry of the Embryo in the Frog (*Rana temporaria*)" by J. W. Jenkinson. However, the term only came into wide use in the 1920s when it began to appear in textbooks, e.g., F. C. Mills, *Statistical Methods* of 1925. The Oxford English Dictionary gives the following quotation from Mills: "The equation to a straight line, fitted by the method of least squares to the points on the scatter diagram, will express mathematically the average relationship between these two variables." Fig. 1 provides an example of scatterplot diagram.

Scatterplots are mainly appreciated for their ability to reveal nonlinear relationships between variables. Moreover, scatterplots are typically used to identify correlations between variables, with a certain confidence interval. Another usage for the scatterplot is to compare similar data sets. Since the main problem of multivariate data is to correctly understand and analyze them, pointing out relationships, patterns, or outliers, a scatterplot provides a suitable visualization tool for multivariate data due to its intrinsic features.

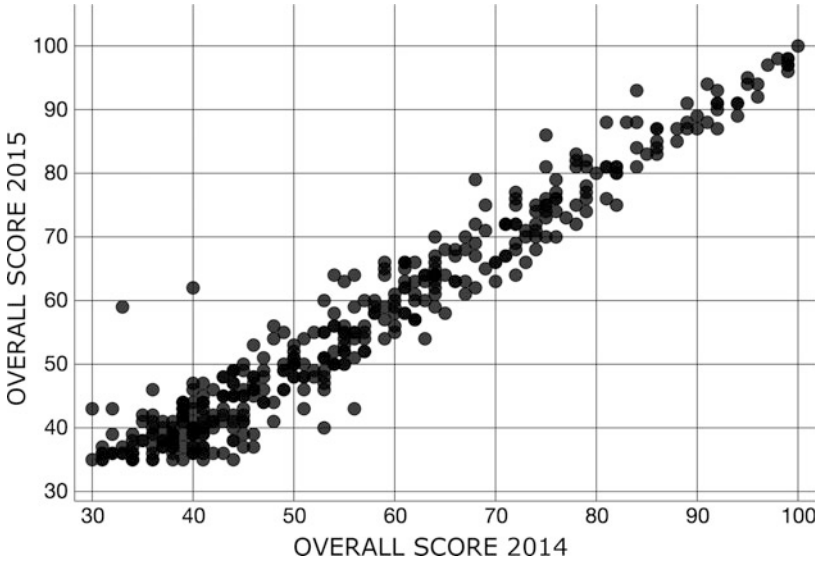
Usage

Different scenarios lead to different tasks when dealing with multidimensional visualization techniques. As defined by Valiati (2005) and further described by Pillat et al. (2005), five major tasks can be considered as objectives a user might want to fulfill when using a visualization tool to display or analyze multivariate data: identify, determine, compare, infer, and locate. Scatterplots can be used to assess all these different tasks and have been applied to data in many different fields of use, such as automotive, finance, pharmacology, environment, weather forecast, telecommunication, food, and many others.

Identify

This task refers to any action of finding, discovering, or estimating visually:

- Properties like symmetrical or asymmetrical distribution, values or dispersion
- Correlation, data dependency or independency
- Similarities or differences



Multivariate Visualization Using Scatterplots, Fig. 2 This scatterplot suggests a correlation between the two displayed variables

- Clusters as a result of similarity, continuity, proximity, or closed shapes
- Thresholds, patterns, data variation

The identify task takes place anytime the user analyzes the chart with the purpose of finding, estimating, or discovering new information about the data. The task ends when the user finds the information he/she was looking for or the current goal changes. Figure 2 shows an example of scatterplot that clearly suggests a linear correlation between the displayed variables.

Determine

This task corresponds to the action of calculating, defining, or precisely designating values such as:

- Mean, median, variance, standard deviation, amplitude, percentile
- Sum, differences, proportions
- Correlation coefficients, probabilities, or other statistics such as hypotheses test

This task begins when the user needs to calculate a specific value and ends up when the calculation is completed. Figure 3 shows a scatterplot that allows to derive the precise value of each point in order to compute precise calculations such as the mean value.

Compare

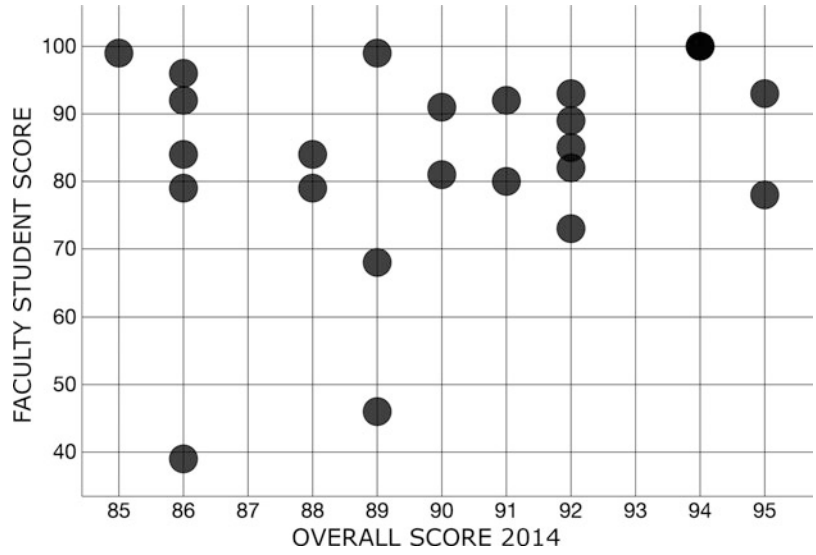
This task takes place when the user wants to compare data that have been previously identified, located, visualized, or determined. The user may compare data to analyze dimensions, data items, clusters, properties, proportion, values, locations and distances or visual characteristics. The compare task is an analytic task the user performs specifically if he/she compares data items displayed in the graphical visualization. Figure 4 shows a scatterplot configuration that enhances the comparison task.

Infer

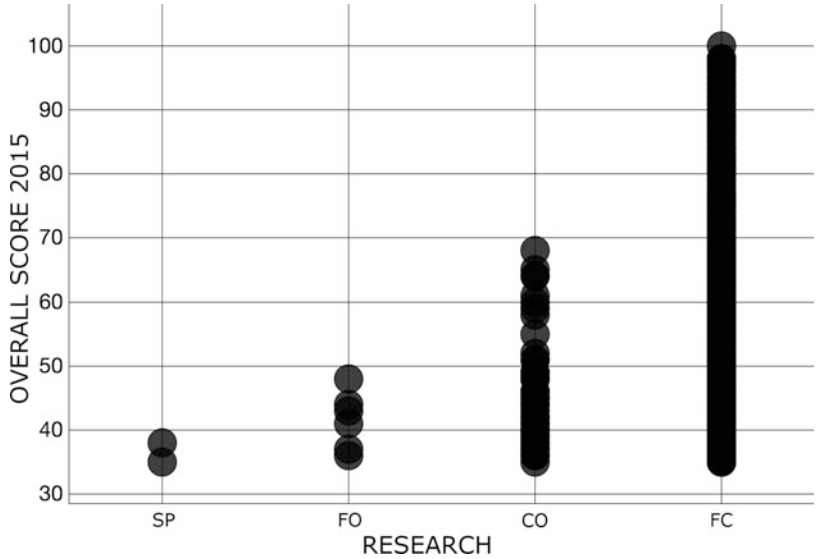
This task refers to the action of inferring knowledge from the visualized information, such as defining hypotheses, rules, probabilities or trends, attributes of cause and effect. This task usually takes place after determining, identifying, or comparing information, and it is performed as part of the mechanism of data analysis, thus it may not be completed at once, requiring consecutive applications of the other visualization tasks. By analyzing Fig. 1, it is possible to infer a hypothesis, e.g., that the y variable is the cause of the trend of the data.

Locate

This task refers to the actions of searching and finding information in the graphic representation: they can be data points, values, distances, clusters,



Multivariate Visualization Using Scatterplots, Fig. 3 A scatterplot visualization that simplify the computation of the mean



Multivariate Visualization Using Scatterplots, Fig. 4 A scatterplot configuration that enhances comparison

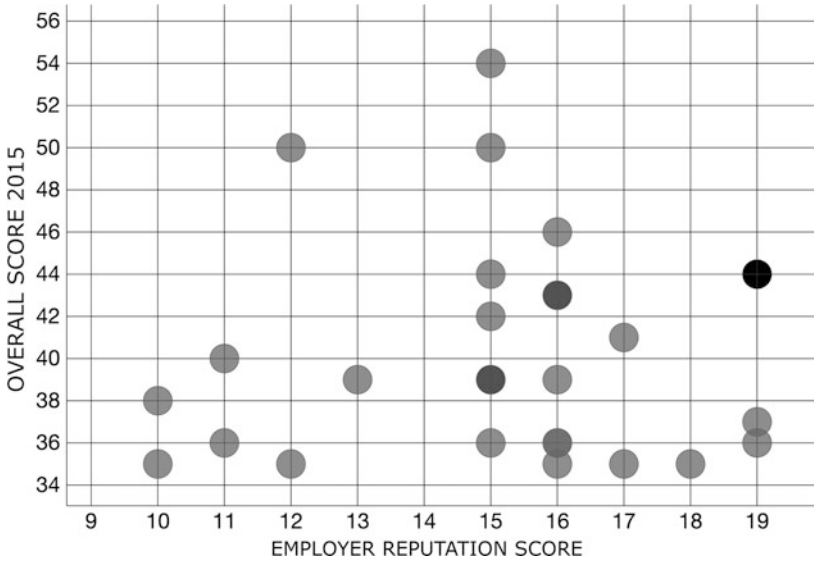
properties, or other visual characteristics. The task begins when the user starts examining the visual representation and finishes when he/she recognizes the desired information. Figure 5 shows a scatterplot visualization that enhances the identification of outliers.

Dimensions

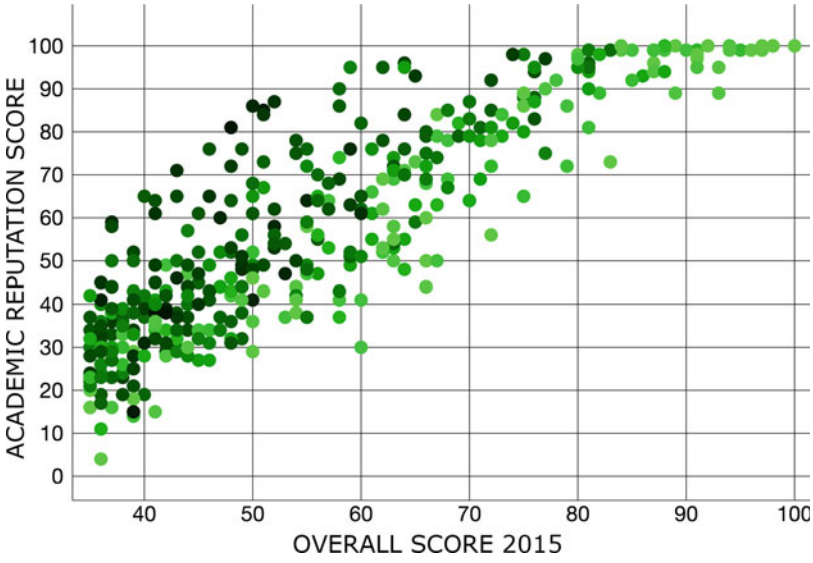
The main problem when using the scatterplot to visualize multivariate data is that its basic version is limited to only two variables, thus making it difficult to correctly visualize and analyze all the data. In order to overcome this problem, different solutions have been proposed through the years to enhance the scatterplot.

Adding Dimensions

Even if the basic scatterplot may display only two variables, various techniques have been researched and adopted through the decades to increase the dimensionality of scatterplots by one, two, or even several additional dimensions. A bidimensional planar scatterplot of two variables X and Y can display additional variables



Multivariate Visualization Using Scatterplots, Fig. 5 A scatterplot visualization that enhances the identification of outliers



Multivariate Visualization Using Scatterplots, Fig. 6 A scatterplot with an additional variable visualized as color

by correlating them to one or more graphical features of the plotted points.

Color

One approach is to show a third dimension through a color map. Colored points on a scatterplot may suggest similarity among values of the same dataset or correspondence among points of different datasets. Moreover, this correlation may be perceived without drawing any connecting line. This technique is particularly powerful since it could also be used to link together an arbitrary number of scatterplots, both different or complementary, such as in the case of a scatterplot matrix, without cluttering or visibly degrading any of them. This solution can increase significantly the effectiveness of such visualization with respect to the sum of the individual unlinked scatterplots. Colors can also be used to enhance the perception of a variable already displayed by another effect (such as an axis). Figure 6 shows a scatterplot that displays an additional variable through colors.

Size

A further option to provide an additional dimension to the scatterplot is to vary the size of the points. Anyway, this option may lead to occlusion problems if the plot does not provide proper scaling on the two axis. Figure 7 shows a scatterplot with a variable mapped on the size of the points.

Shape

Another approach is to add a third dimension changing the shape of the points. Instead of using only points, each element of the dataset could be drawn as different kinds of glyphs depending on a third variable. This option leads to further possibilities in terms of the paradigm used to choose the shape. One option is to display the points as "flowers," relating the variable to the number of "petals" to display. Another option is to display polygons and relating the number of sides to the variable. Moreover, various glyphs, clearly distinct among them, could be used to represent different datasets. Figure 8 shows a scatterplot that uses the shape of the points to display additional information.

Orientation

Another possibility when displaying points as shapes is to represent a third dimension changing the orientation of the shape. Usually, a dot or line is drawn orthogonally to the perimeter of the shape to better identify the reference point for the orientation. Figure 9 shows a scatterplot that displays an additional variable through the orientation of the points.

Error Bars

The uncertainty is the variability related to a specific variable of the dataset for each point. It provides a generic idea of how precise the measurement of the reported value is or how far from the recorded value the real value might be. This information is usually reported through error bars if it is related to a variable mapped on the x or y axis (or both). Figure 10 shows three examples of error bars. Error bars require additional space around the points to be correctly displayed due to the chance of overlapping between points. For this reason, they are usually adopted only if the points of the scatterplots are very scattered and occlusions do not occur. Otherwise, the use of error bars would greatly affect the understandability of the representation. As a result, the use of error bars limits the number of different graphical effects that could be combined on the same scatterplot and should be avoided when displaying more than three or four variables.

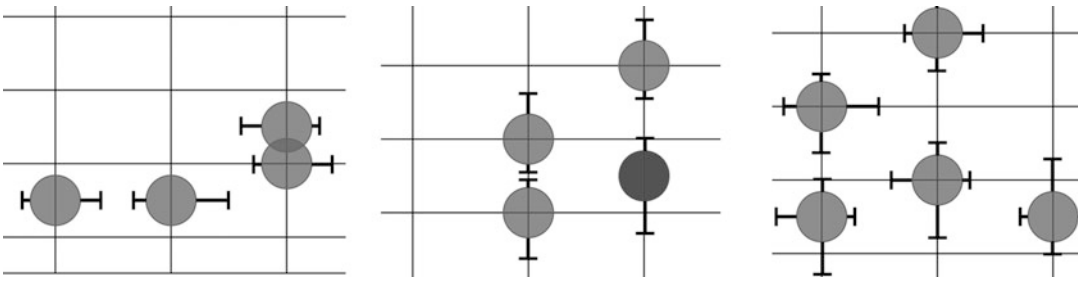
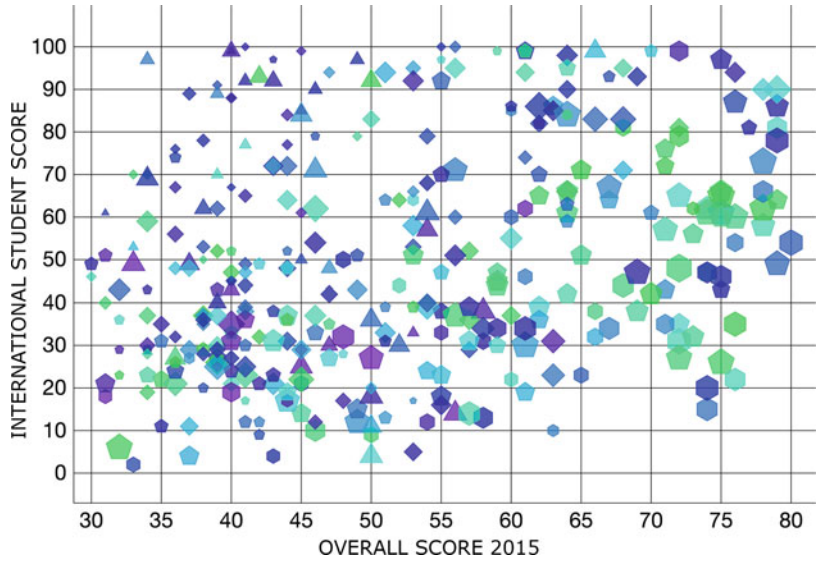
Multivariate Visualization Using Scatterplots, Fig. 9 A scatterplot that displays an additional variable through orientation



Multivariate Visualization Using Scatterplots, Fig. 10 Three examples of error bars



Multivariate Visualization Using Scatterplots, Fig. 11 A scatterplot that displays multiple variables through different effects

Adding More Dimensions Concurrently

It is possible to use simultaneously more than one of these techniques, independently, to obtain even high visual dimensionality. Figure 11 shows an example of such a scatterplot. However, this is recommended only if the graphical effects are clearly distinguishable, otherwise the visual clarity and benefits of displaying more dimensions at the same time will promptly worsen. Many studies, like the one by (Demiralp et al. 2014), have been carried out to understand how visualization design can benefit from taking into consideration perception, as different assignments of visual encoding variables such as color, shape, and size could strongly affect how viewers understand data.

Dynamic Visualizations

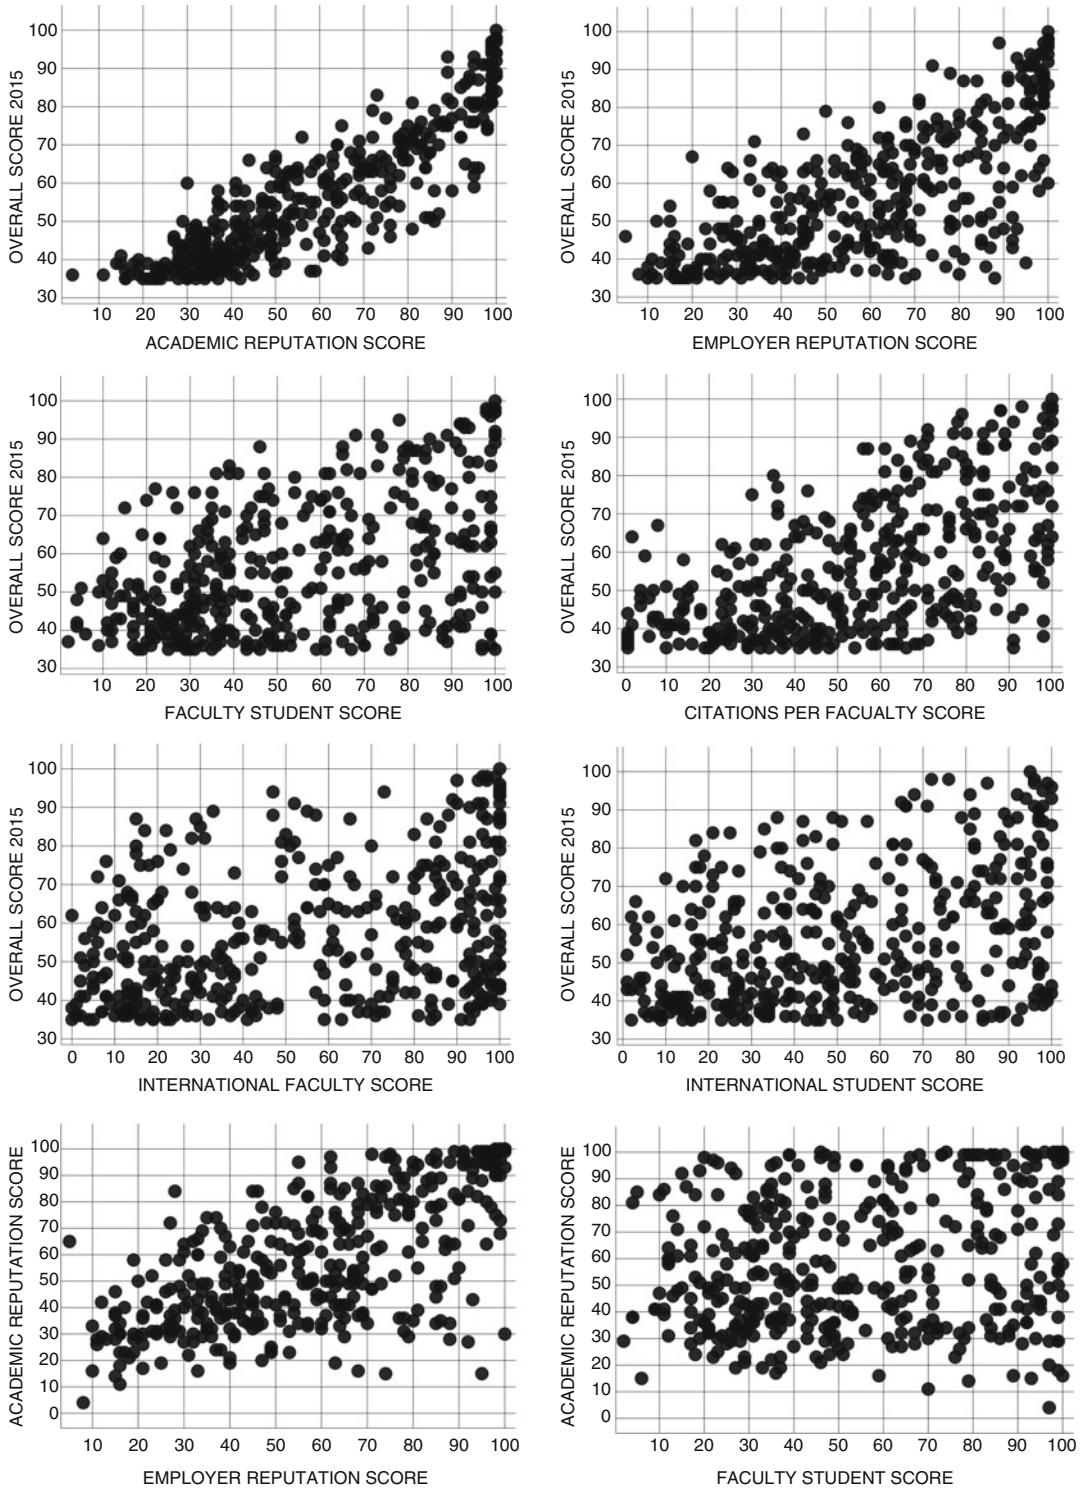
Even if scatterplots are typically used to display static data, nevertheless they can be very useful when applied to display data that could change dynamically, moreover if the change may be controlled by the user. More complex graphical effects such as animation may be adopted in this case to enhance the comprehension of data as they change over time. This is the case of data characterized by one or more time-related variables, such as stocks values in finance or weather conditions in forecasting.

Scatterplot Matrix

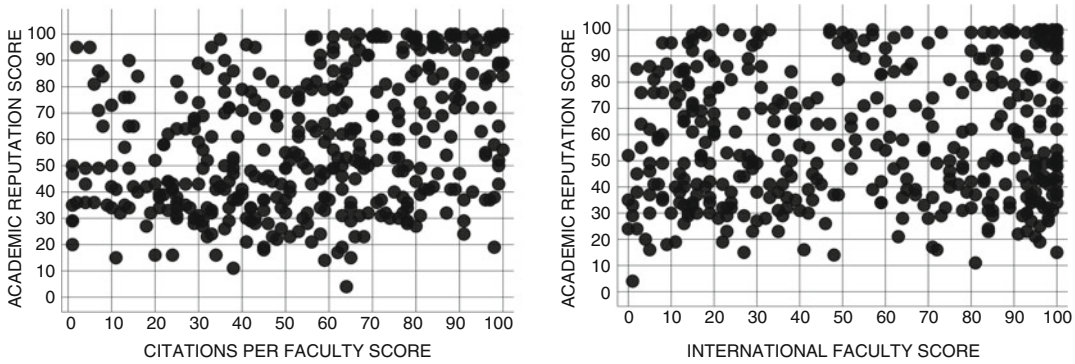
The simplest approach to adapt the scatterplot to multivariate data is to produce a series of scatterplots for each pair of variables and display them together on a single screen or page. This visualization technique is called scatterplot matrix and for k variables it requires k(k-1)/2 pairs and therefore scatterplots. Unfortunately, this solution presents a major problem: analyzing all the scatterplots may require a lot of time, depending on the number of variables, thus this solution is not optimal when dealing with time-related tasks. To overcome this problem, different visualization techniques may be adopted to interact with the dataset and simplify data comprehension. Figure 12 shows an example of scatterplot matrix.

Brushing

Brushing is the action of selecting a subset of the points displayed on the scatterplot. Four brushing operations have been defined by Becker and Cleveland (1987): highlight, shadow highlight, delete, and label. To perform these operations, it is necessary to resize a rectangle, called the brush, over one of the scatterplots. The corresponding points on each different scatterplot are then affected by the chosen operation. The brush can be moved to different regions of the scatterplot by



Multivariate Visualization Using Scatterplots, Fig. 12 An example of scatterplot matrix



Multivariate Visualization Using Scatterplots, Fig. 12 (continued)

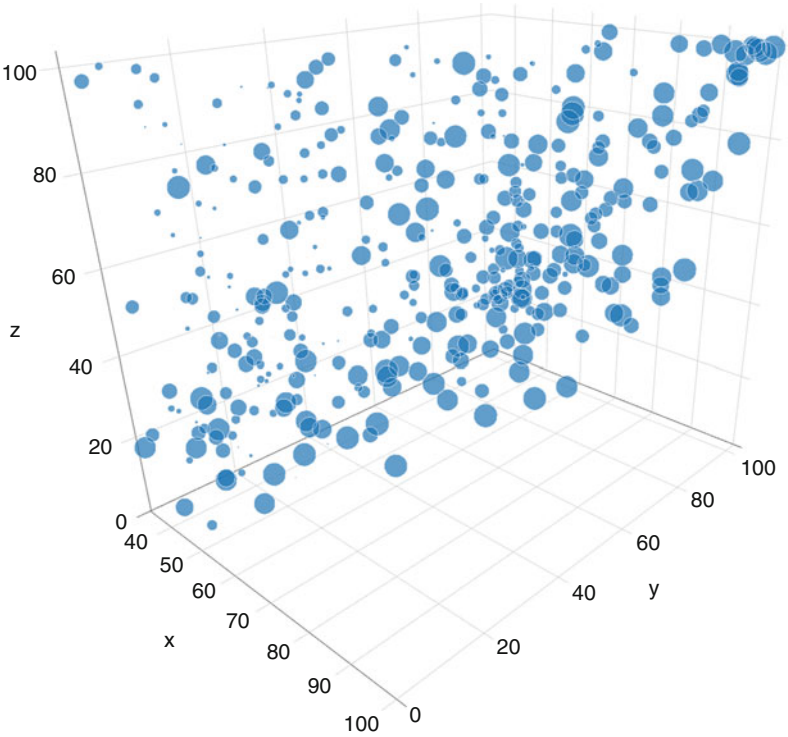
moving the mouse. At any time, the user can stop the brushing operation, change the shape of the brush or the chosen operation, and then resume the brushing.

Dimension Reordering

One of the problems when dealing with scatterplot matrixes is to simplify the understandability of the data. One possibility is to change the way the scatterplots are displayed and ordered to enhance the presence of clusters, patterns, or trends. Different approaches have been investigated and adopted, such as the systematic dimension reordering approach of Ankerst et al. (1998) where similar dimensions in a multidimensional dataset are placed next to each other. Using a scatterplot matrix it is possible to order independently rows and columns. In the systematic dimension reordering approach, similarities are displayed on the column and dissimilarities on the row order.

3D Scatterplots

Another way to display multidimensional data through scatterplots consists in adopting a 3D visualization. 3D scatterplots exploit the third dimension, representing three data dimensions on the x, y, and z coordinates, in a three-dimensional space. The third dimension allows the user to interact with the scatterplot to change the viewport (with two or three degrees of freedom). Hypothetically, more coordinates could be added to the model, leading to an n-dimensional spatial representation. Since 3D scatterplots are represented on displays as 2D images, the 3D representation needs to provide useful hints to properly display depth and avoid occlusions or misinterpretations of data. Occlusions can be addressed also in 2D representations by using another data dimension for depth sorting. The latter can also be compared to a full 3D scatterplot where the only difference is the missing rotational interaction in 3D. This mapping also requires three axis: two for spatial positions and one for sorting. 3D scatterplots make it possible to obtain more flexibility in the data mapping simply avoiding to fix certain data dimensions to only certain specific scatterplot axis: this could be obtained allowing the user to exchange the dimensions mapped on each axis, either by swapping the dimension of one or two axis or by manipulation of dimensions. 3D scatterplots may also consist of more complex versions, including additional graphical effects (color, size, orientation, shape, etc.) to represent additional information related to the displayed data, guideways (reference lines from the data up to some reference points) and combinations of scatter data with additional objects as fit surfaces. A common application of the 3D scatterplot is to show both experimental and theoretically adjusted data in order to be able to determine the points of agreement. In Fig. 13, a scatterplot can be observed in three dimensions that makes use of the size of the spheres to map an



Multivariate Visualization Using Scatterplots, Fig. 13 A 3D scatterplot displaying an additional variable through size

additional attribute. Overall, 3D scatterplots have certain advantages and limitations with respect to 2D models, as depicted by Escudero et al. (2007).

Advantages

In a 3D scatterplot, maintaining the same density of points as in a 2D scatterplot involves increasing the number of experimental data to be displayed (larger sample space). If the number of points of the initial 2D scatterplot is maintained, there is a greater discrimination of the relations between variables, since a characteristic is added to the data. The use of volume visualization in 3D scatterplots provides the possibility of generating glyphs by procedural techniques: the form of the glyphs is computed by a mathematical formula which determines the number of lines or sides (Ebert et al. 2000). These techniques allow the user to increase the number of dimensions of the data to be shown by exploiting the shape of the glyphs, thus taking advantage of the preattentive ability of the human visual system to discriminate forms. To obtain the best result from a 3D scatterplot, it is necessary to achieve an efficient attribute mapping and to provide the necessary interaction tools to navigate and examine the data: these requirements enhance the expressive power of a 3D scatterplot and allow the user to analyze complex relationships among multiple variables.

Limitations

It is not advisable to abuse multidimensionality if it is not absolutely necessary and the result is not visually illustrative. Moving information representations from 2D to 3D is not a simple task, since the extra dimension may greatly affect how information can be presented and interpreted. The visualization must make an efficient use of the additional dimension and avoid that the new representation is misinterpreted by the user as a consequence of an inappropriate mapping. Special consideration must be given to the perception of spatial distance. The size of the objects can cause the user to not perceive the correct perspective of the information shown: it is difficult to discriminate among the different depths of the objects, and to address this problem it is necessary to provide

the appropriate interaction tools. A disadvantage arising from the use of three-dimensional objects is occlusion, which occurs when one object covers another or occupies the same spatial position for two coordinates in the 3D representation. This type of problem occurs mainly when the density of data items to be displayed is large or when simply a very large object is positioned in front of smaller objects.

Remarks

The reason behind such a various enumeration of scatterplot solutions is that none of them could be considered the best version: each implementation could be less or more useful depending on the specific task the user intends to solve. Eventually, more than one kind of scatterplot should be used for the same dataset to address different tasks. Overall, a simple classification could distinguish among 3D scatterplots, scatterplot matrices, and standard scatterplots with additional dimensions. 3D scatterplots are more useful when dealing with a huge amount of data with a dense distribution on the x and y axis, allowing the user a better analysis through spatial navigation. Scatterplot matrices are more useful when the task is to search for correlations between two variables of the dataset: each scatterplot of the matrix may display two variables, and the user just need to analyze them all, one by one. For other tasks, the best solution is adding dimensions to the standard scatterplot, as different graphical effects provide a better insight on the data depending on visual perception criteria, as investigated by Demiralph et al. (2014) and many others.

Definition

Narrative design combines game design and game writing. It uses the mechanics of game design to create a dramatically compelling story to the game player. In a broader sense, narrative design is a unity of carefully selected game mechanics that would adhere the story elements in either textual or symbolic/visual form with the aim to fulfil the desired gaming experience for the players. Narrative design can be textual, visual, or aural. It is usually a tight bond of all these mediums telling the story directly through players' senses in a form of gaming experience that was set by the game designer.

Introduction

A narrative designer works together with the rest of the game development team from the conception to the release of the game (Heussner et al. 2015). The collaboration is closest with the game designer, who is responsible for the vision and idea of the whole game. The narrative designer focuses on bringing in and integrating the story so that it seamlessly fits into the game design and complies with the game mechanics and art style. Narrative design requires a special set of skills, and many writers coming from more traditional media might find it difficult to give up authorial control and to adapt to work within the confines of the game system and as a part of a multidisciplinary development team. Furthermore, the narrative designer commonly directs the graphics and audio team in creating the right environment, character design aesthetics, and all other visual elements that would highlight the story content for more immersive gaming experience.

Narrative Design, Fig. 1 In traditional storytelling, once the author has created the story, it is presented the same way to all spectators. In interactive storytelling, the narrative designer is responsible for the characters and events in the storyworld, which are used to generate the story in line with the player's individual preferences and expectations

What sets narrative design apart from traditional storytelling is the player's influence on the story being told. This creates a friction that the narrative design has to solve. There are different approaches on how to handle this depending on how much narrative control is given to the player. The narrative designer can employ different methods for guiding the player to make impact on the story progression, which we will present later in this article.

Academic research on digital storytelling has a long history (Koenitz et al. 2015), but from 1990s onwards it has focused especially in interactive narratives. Seminal works in this field include books by Laurel (1991, 2014) and Murray (1997, 2017) and the proceedings of the International Conference on Interactive Digital Storytelling (http://icids.org/). One of the key problems tackled by the research is the role of the player's narrative agency with respect to the author's control over the story, which we will discuss next.

Narrative Control Versus Narrative Freedom

Interactivity is the key difference between games and other forms of media, and game technology provides a new medium of expression where an essential part of experiencing the story happens through a direct participation with the narrative progression. In traditional storytelling, the flow of the story is linear with clear stream from the author to the audience. In interactive storytelling, the audience has an active part in shaping up the story and co-creating it with the author (see Fig. 1). Outside of the digital realm, this kind of storytelling happens, for example, in improvisation theater and (live action) role-playing games. Also, teaching and tour guiding are such endeavors where the audience participation – ideally – has a significant effect on the outcome of the story. This also opens the topic of diversity in experiencing the

narrative within a solitary gameplay or as a part of a group effort.

Interactivity allows the player to have *agency* in the story, which means that the player can make meaningful choices affecting the story's direction. This requires that the game conveys information on the possibility of a choice to the player. Moreover, the player must, at the time of making the choice, have an idea on the possible consequences of that decision. Finally, to have agency, the ramifications of the choice in the story must be seen immediately and – to maximize the effect – they should also show an effect at the end of the game.

The requirement of narrative agency – or freedom of choice – contradicts with the idea of a story being authored. The player can refuse to follow the intended story and do something else instead. For example, imagine a game based on the film *Star Wars: A New Hope*. Now, the player controlling the character of Luke Skywalker could refuse to leave Tatooine preferring to lead a life of a farmer. How could the author persuade the player to follow the intended story and leave the planet with Obi-Wan Kenobi and the droids?

One possible answer is to increase the limits of the freedom of choice and forcing the player into a certain direction – either by hinting or even by coercion. This resembles the situation in the film *Stranger Than Fiction*, where the main character is hearing a voiceover of his life. At some point, he decides not to follow it and instead goes back to his apartment only to discover how hints (e.g., mail, news program, commercials) turn into coercion (wall being bulldozed down) forcing him eventually to follow the voiceover's story (this same conceit is also used in the game *The Stanley Parable*).

This problem is called the *narrative paradox*, and there are different proposals on how to solve it. One possibility is to take a high-level approach that posits that the player enters into a contract with the author meaning that the player will obey the constraints of the storyworld (Adams 2013). The same happens in games in general: the game designer is the one setting up the moral of the game world (i.e., which actions are "good" and which "bad"). For example, a pacifist stance is not "good" in the moral system of a first-person shooter game, because it makes impossible proceed in the game.

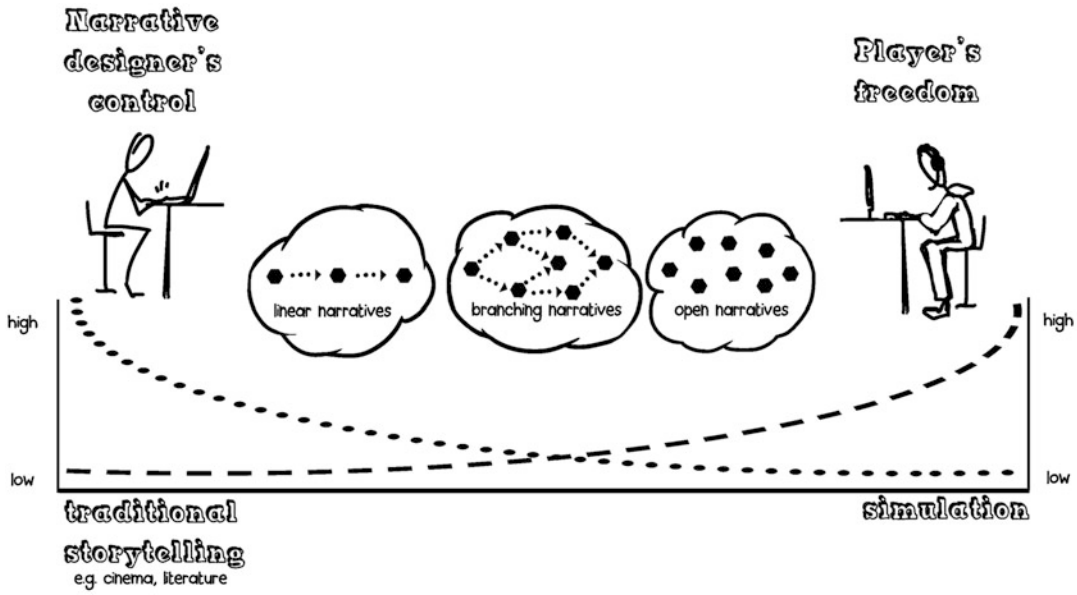
A design-oriented solution to the narrative paradox has two opposite approaches (Smed 2014). Author-centric approach puts the author's control in the first place. This leads to having a part of the software, a *drama manager*, which acts as a proxy for the author and tries to manipulate the game world and its entities so that the player follows the intended route lined out by the author. Naturally, this can lead to a situation called "railroading" where the players – regardless of their skills and abilities – are at the mercy of the game story.

Conversely, the character-centric approach sees the author as a Newtonian god, setting up the game world and its entities and leaving them alone to interact once the game starts. This so-called *emergent narrative* depends highly on the underlying simulations, especially the computer-controlled characters, but gives no guarantee whether a story comes up from this process. Naturally, this can be enhanced by reintroducing the drama manager as a behind-the-scenes partaker, which the characters can consult for making dramatically compelling decisions, leading to a hybrid approach.

Designs for Interactive Narrative

Figure 2 illustrates the continuum of narrative types used in games. As the narrative paradox indicates, the narrative designer's control over the story and player's narrative freedom exclude one another: the higher the narrative designer's control, the less narrative freedom the player has, and, conversely, high narrative freedom of choice means reduced control for the narrative designer. At one extreme, we have the case where there is no freedom, which constitutes a reduction back to traditional linear storytelling (e.g., cinema, literature). At the other extreme, we have no authorial control of the narrative, and the game is reduced to just a simulation.

Between the extremes we have three different approaches to incorporate narrative into games (Heussner et al. 2015; Zeman 2017). The most widely used is *linear narratives*, where the story



Narrative Design, Fig. 2 The spectrum of narrative types in games

progresses linearly (e.g., through cutscenes between the levels or environmental changes) but the player has freedom in the gameplay. This means that every player will every time encounter the same story in the same order. Although the player, therefore, lacks narrative agency, the story can be woven into the level design such a way that the player's actions seem to have an influence in the story as well. For example, the killing of a level boss can be followed by a cutscene, where the allies of the boss get involved in the conflict. Although the killing of the boss was necessary for the player to proceed in the gameplay, now it seems to have repercussions in the story as well. This pseudo-agency provides the players with a feeling that they can affect also the story.

Ideally, each narrative choice would lead to a new and different situation meaning that the player could try out all possible scenarios like in the film *Groundhog Day*. However, this full branching leads to a combinatorial explosion, where the shear amount of narrative alternatives becomes infeasible to handle. In practice, these kinds of *branching narratives* use pinch points, where the divergent paths join reducing the number of alternatives. An early and nondigital example of this approach is the *Create Your Own Adventure* book series, where the reader has to choose at the end of a chapter how the story continues and then skip to the indicated page to continue reading. A classic example of a game using branching narrative is *Indiana Jones and the Fate of Atlantis*, where the story early on branches to three alternative paths – team, wits, or fists – and later on a pinch point brings all three paths back together.

In branching narratives, a key question is the critical path, which connects the start to the end of the narrative. Maintaining the critical path is an important task for the narrative designer so that the story progresses no matter what the player chooses. To enlarge the storyworld the designer can add short linear narratives that are separate from the critical path and optional to the player. They can be individual quests or tasks that the player can take, which can expand the overall fabula of the game.

Open narratives present the biggest challenge to the narrative designer. Here, there is no imposed sequence for the narrative events but each player can take their unique path. These

kinds of sandbox games can include preconditions for the narrative elements, which provide some structure. For example, the game *Her Story* has a complete but deconstructed underlying story, which can be experienced in any order by entering keywords to the game's internal search engine. However, the players are most likely to search terms related to events happened recently, hence creating a loose structure into the open narrative.

Another possibility to create a structure into the openness is to scatter the story throughout the levels (i.e., each level has its own set of open narratives). Also, some story elements can be threaded so that they form short linear sequences. These (possibly optional) threads can include missions, quests, jobs, or rescues taken inside of a larger context.

The Form of Storytelling

Although narrative design is often thought as textual, it can also include visual or aural elements – or even omit the textual narrative and focus on other forms of conveying the story. Let us look and compare how some games present a complex narrative design to a player using different forms of storytelling. A common feature to these games is they have a deep narrative design with a main protagonist that reflects to the players' preferences in a gameplay – the player can decide the course of the narrative from aggressive/achievement-driven to more adventurous/story-driven experience.

To provide an open world experience with a feel of free exploration in *Horizon Zero Dawn,* the narrative designer and the game designer have used a variety of traditional methods of literary and rhetorical allegory in revealing the story. Conversely, in games such as *ABZÜ* or *Journey*, the creators have focused fully on the visual storytelling methods with an almost complete absence of textual content in the game. In such an approach, semiotics theory (Schapiro 1969) and iconography (Panofsky 2003) have an essential role in creating the interactive narrative experience for the players, where even the symbolism of a color or the type of light and the texture in a scene can provide necessary information for the player to progress in the game. Naturally, this makes high demands on the graphics team, since their task is to translate the narrative design into a visual narrative by using all possible tools from semiotics, psychology, and symbolism theories. Moreover, this visual translation of the story-driven experience needs to be easily understood via a seemingly simple user interface design and clear indicators in the game environment that guide the player in the story progression.

The game *Life is Strange* is based on more traditional storytelling methods, where the player makes clear choices from a given branching narrative. The story progresses as an episodic interactive narrative, which is also common in visual novels and interactive fiction. In these games, narrative designers focus on specific segments of the story that give a full loop and a sense of conclusion by the end of the game, and, at the same time, the story has enough of open-endedness that it can continue in another episode as a sequel, or even completely new game-titles that refer to the previously given narrative experience. Still, the follow-up game can usually be played and experienced without having played the previous game in the series, which is the case in adventure games such as *Zelda*, *Tomb Raider,* or *Assassin's Creed*. The storyline binds all the games – and the big narrative construction that represents the game world and all its content – under one title. The introduction and tutorial parts of a game serve as an "onboarding" to the given narrative framework for the players not already familiar to the preceding games in the series.

Conclusion

Narrative design takes the challenge of combining stories and games. This requires an understanding of the needs of interactivity and narratives. The end result should be a game that is dramatically compelling without hindering the player's agency

too much. To realize this, the narrative designer has three broad approaches – linear narratives, branching narratives, and open narratives – to choose from and can then refine it to fit in with the gameplay and the story being told. Contemporary game design tendencies highlight the importance of an individual gameplay experience that accommodates to the player's personal preferences. Therefore, the player is provided with necessary tools to shape the narrative progression according to their own individual expectations and desired game experience.

Every game – no matter how simple or complex its structure may seem – has a goal for the player to achieve. Narrative design is where the game mechanics, visual and aural content come together to give the feeling of a purposeful experience in pursuing that goal.

Synonyms

Ludonarrative; Video game narrative

Definition

Today, no generally accepted definition of video game narrative exists. The academic discourse has pointed out ontological and phenomenological differences to more traditional forms of narrative, and therefore, the relationship to established scholarship in narratology is complex. In the field of video game studies, narrative aspects of video games are often described in contrast to rule-based aspects. A wider scan of related fields reveals additional positions. Ludonarrative is variously understood as a structural quality of the video game artifact, as an experiential quality during the experience of a video game, or as a high-level framework to understand video games. Finally, a number of scholars emphasize the difference to traditional manifestations and therefore work towards specific theories of video game narrative. While all legitimate by themselves, these different usages of "narrative" in the context of video games are often not clearly distinguished in professional or academic discourse and can lead to considerable confusion. It is therefore essential to scrutinize the particular context and underlying assumptions when approaching the topic. This state of affairs puts particular responsibility on scholars to identify

the origins of their understanding of video game narrative and define their particular usage of the term in contrast to earlier applications.

Introduction

Video game narrative has been the topic of much scholarly and professional debate (see "Narratology vs. Ludology debate" below). Both academics and practitioners are divided on the potential and scope of narrative in regards to video games. A foundational issue of these perspectives is the lack of a shared understanding of "narrative" – the term might be variously used to mean an ornamental function to provide context (Juul 2005), a structural quality of the video game artifact (Fullerton et al. 2008), an experiential quality during the experience of a video game (Pearce 2004; Salen and Zimmerman 2004), or a high-level analytical framework to understand video games (via textual analysis (Fernández-Vara 2014)). Each of these perspectives represent valid approaches; however, implicit definitions of "narrative" are prevalent in academic and professional discourse on video game narrative, and thus the particular meaning used is often not readily accessible. The topic therefore needs to be approached with particular scrutiny to carefully unpack the underlying assumptions of a given academic paper, professional publication, or audience reaction. In other words, one scholar's "experience dimension" might be another scholar's "narrative" and one developer's "level design" might be an audience member's "narrative." As a generally accepted definition of "narrative" (and the related term "story") seems elusive for the time being, scholars and professionals working on video game narrative are highly encouraged to make their respective definitions and underlying assumptions explicit.

Analytical Perspectives: Understanding Video Game Narrative

Early Perspectives

Early scholarship on video games understands narrative as a natural ingredient, for example, the first PhD thesis on the topic in 1985 by M.A. Buckels analyses the first text adventure as a "Storygame": Interactive Fiction: The Computer Storygame "*Adventure*" (Buckles 1985). Later publications by Brenda Laurel (Laurel 1991; Laurel 1986) also center on narrative. Theorists of Hypertext literature such as Jay Bolter (Bolter 1991) and George Landow (Landow 1992), intent on using computers as means to implement post-structuralist ideas of narrative, developed analytical frameworks and introduced sophisticated concepts like that of variable "contours" (Bernstein et al. 1992) – narrative forms that enable their own reshaping. It was however Janet Murray's seminal book *Hamlet on the Holodeck. The Future of Narrative in Cyberspace* (Murray 1997) that alerted a wider audience of the narrative potential of the digital medium. The essence of Murray's book is not in the vision of the holodeck itself (a frequent misunderstanding), but instead in the development of two sets of related and influential analytical categories for interactive forms of narration: the affordances (participatory, procedural, spatial, and encyclopedic) and aesthetic qualities (immersion, agency, transformation) (cf. (Harrell and Zhu 2009; Mason 2013; Tanenbaum and Tanenbaum 2015; Wardrip-Fruin et al. 2009) for further developments of these categories and (Roth and Koenitz 2016) for an application in user experience research).

The "Narratology Vs. Ludology" Debate

This academic debate is foundational for the field of games studies and one of its main underlying assumptions, that of a dichotomy between dynamic, rule-based games and static, immutable narratives. This perspective featured prominently in the inaugural issue of the journal *Games Studies* (gamesstudies.org) (Aarseth 2001; Eskelinen 2001; Juul 2001). The debate encapsulates two separate topics, the question of video games as a medium for narrative and the applicability of analytical methods from the field of narratology to computer games. It started in 1999 when Jesper Juul proclaimed: "The computer game is simply not a narrative medium" (Juul 1999), a position Juul later modified (Juul 2001); in the same year, Gonzala Frasca emphasized the need for

ludology in contrast to narratological analysis. Furthermore, he proposed the term "ludology" to mean the "discipline that studies game and play activities"(Frasca 1999). Frasca later defined games as "simulations" with distinct rhetorical possibilities in contrast to narratives (Frasca 2003a) (cf. Bogost's (2007) further development of this perspective).

The pioneering ludology scholars in particular directed their criticism against Janet Murray and Henry Jenkins. In Murray's case, it was her analysis of *Tetris* as a narrative (of an overwhelming onslaught of tasks in contemporary society) in *Hamlet on the Holodeck* (Murray 1997) that provided a particular target for their critique, and in the case of Henry Jenkins it was his understanding of transmedia narratives and of video game design as "narrative architecture" (Jenkins 2004). In that paper, Jenkins identifies a number of productive avenues for game narrative: *evocative*, *enacted*, *embedded,* and *emergent* narrative. *Evocative* narratives reference prior work, for example, a Star Wars Game that refers to the movie series. *Enacted* narratives allow the user to act out roles within an existing narrative universe, for example, as a hobbit in a Lord of the Rings game. *Embedded* narratives convey information by means of narratively meaningful objects and encounters within the game space. Finally, Jenkins describes *emergent* narratives in games like *The Sims* that provide players with the tools to construct stories of their own.

The debate continued at conferences and publications and is most visible in the dialogic form of the electronic version of the edited collection *First Person* (Wardrip-Fruin and Harrigan 2004), for example, Eskelinen's response (Eskelinen 2004) to Jenkins (2004) or Aarseth's (2004) response to Murray's article (2004). After 2004, the intensity of the debate decreased considerably and Murray attempted to put an official end to it in a keynote speech at the 2005 DIGRA (Digital Games Research Association) conference (Murray 2005).

However, the underlying issues cannot be considered resolved. Neither Murray nor Jenkins have ever made claims to be narrative theorists and are better understood as "narrative expansionists" with a purpose to expand our understanding of narrative phenomena (respectively of interactive digital narratives and transmedial narratives). Indeed, Gonzala Frasca's thoughtful contemporary analysis of the debate "Ludologists love stories, too. Notes from a debate that never took place" (Frasca 2003b), rejects the label of narratology for Murray and Jenkins (cf. for actual narratological positions (Ryan 2006; Ryan 2001) or (Neitzel 2014)). Frasca instead issues a challenge to discuss a third, "narrativist" position, which he associates with attempts to create interactive experiences based on literary theory (e.g., Mateas 2001). This interesting perspective of a "third position" has yet to receive sufficient attention, although Eskelinen applies the term later to refer to Murray, Jenkins, and Ryan (Eskelinen 2012). In addition, both the main protagonists (e.g., Aarseth (2012, 2014), Murray in the new edition of *Hamlet on the Holodeck* (Murray 2016)) and additional scholars (e.g., (Calleja 2013, 2015; Ryan 2006; Simons 2007)), continue to reference and discuss the original positions. Eskelinen's recent project of a more universal theory of narrative (Eskelinen 2012) merging narratology (mainly Genette (Genette 1980)) with Aarseth's earlier work on cybertexts (Aarseth 1997) attempts an integration of narrative and games, yet its own persistent distinction between digital and nondigital forms points to the limits of an approach that insists on a media agnostic position (cf. Nausen's warning about "media blindness" (Nausen 2004)). Eskelinen's text so far had limited impact on the ongoing debate.". Conversely, the editor of a recent collection of essays (Kapell 2015) reiterates Frasca's argument that the debate truly never took place and that the questions the debate poses are still unresolved (also see (Mukherjee 2015)).

Therefore, the foundational dichotomy is still influential in video game studies and related fields and by extension in the video game industry, as can been seen in the related term "ludonarrative dissonance" (Hocking 2009) meant to describe a situation of supposed conflict between gameplay and narrative. An example of ludonarrative dissonance would be a character that is portrayed as mild-mannered and considerate in the narrative and yet kills hundreds of virtual characters in the gameplay.

In retrospect, the debate can be seen as productive as far as the development of the study of nonnarrative aspects of games are concerned. However, by entrenching the problematic dichotomy between "game" and "narrative" (maybe most prominently in Juul's book *Half-Real* (Juul 2005)), interest in the understanding of narrative aspects of video games became marginalized in video games studies and consequently, development of specific analytical perspectives has languished. In that sense (and in a somewhat ironic twist) the rejection of narratology has created an analytical void that has more recently been filled by perspectives based in classical (e.g., textual analysis (Fernández-Vara 2014)) and postclassical narrative theory (e.g., Ensslin 2014). One issue with applications of literary-based theory – for example, the reframing of *fabula* and *syuzhet* in a recent paper by Wood (2017) – is that it applies (in this case) structuralist narratology to video games without properly scrutinizing the respective underlying assumptions. This is exactly the danger Aarseth has been warning about: "Do theoretical concepts such as "story," "fiction," "character," "narration," or "rhetoric" remain meaningful when transposed to a new field, [or are they] blinding us to the empirical differences and effectively puncturing our chances of producing theoretical innovation?" (Aarseth 2012). Similarly, Timothy J. Welsh wonders about the influence of established frameworks and asks in a review of Ensslin's book, whether video game narrative has "'matured', as Ensslin suggests, on its own terms," or rather started to produced artifacts that "sufficiently resemble already established artistic practices and critical traditions" (Welsh 2015).

Dissenting Voices

During the main debate Marie-Laure Ryan argues against the rejection of narrative analysis: "The inability of literary narratology to account for the experience of games does not mean that we should throw away the concept of narrative in ludology" (Ryan 2001). She instead proposes to create a new narrative modality for games, in addition to mimetic (enacted) and diegetic (described).

In 2007, Jan Simons offers a pronounced critique of the ludological position: "[. . .] their arguments against narrative and narratology have often been unnecessarily unconvincing." Simons deems the ludologists' arguments "ideologically motivated rather than theoretically grounded" (Simons 2007). In particular, this scholar rejects the distinction between narrative and rules as disproven by emergent narrative in games like *The Sims* series (Wright 2000). Simon's alternative project is in a connection between narrative studies and mathematical game theory (Neumann and Morgenstern 1953). To enable this connection, Simons downplays the importance of the essential category of interaction in video games, of control by the player, and calls it "merely a matter of perspective" already covered in narratology by reader-response theory (Iser 1979). Yet, the kind of cognitive engagement reader-response theory identifies (how readers actively engage with immutable texts in their minds) is not in the same category than the planning and conscious decision-making afforded by video games, where players control the course and outcome (cf. (Koenitz 2010a)). In addition, Simon's focus on outcomes is forced and ignores the fact that games are about experiences, about being "in-game" (cf. (Calleja 2011)). Furthermore, the application of procedural generation to games (e.g., in *No Man's Sky* (Hello Games 2016), a space exploration game in which new planets are procedurally generated) means that some games might no longer have an ending and instead offer infinite gameplay. Yet, even in finite games, players' main focus is not on the ending, but on the experience. To describe a video game from the perspective of the ending means to only incompletely reflect on a 30+ hour commitment and the enjoyment of the in-game experience.

Parallel Developments

Several important contemporary developments in narratology and related fields happened simultaneously with the debate and were not fully reflected in it, most prominently the publication of David Herman's *Story Logic* in 2002. This book marked the "cognitive turn" in narratology, a change from a focus on the analysis of narrative as an aspect of specific forms to an

understanding of narrative as a "forgiving, flexible cognitive frame for constructing, communicating, and reconstructing mentally projected worlds" (Herman 2002) – a flexible definition that can also be applied to video game narrative. Indeed, Marie-Laure Ryan (2006) criticizes the ludologists for basing their critique of narratology on outdated positions (an argument repeated by Calleja (2009)), especially Prince's restricted (and later revised) definition in the first edition of the *Dictionary of Narratology* (Prince 1987) which foregrounded diegetic modes of narrative (the verbal representation of events - "telling") requiring the existence of a narrator, while seemingly rejecting mimetic modes of narrative (the direct presentation of speech and action – "showing"). Ryan therefore rejects the notion of the incompatibility between narratology and ludology and proceeds to locate game narrative with *paidia,* referencing Caillois' (1961) distinction between two kinds of play: *paidia* and *ludus* (essentially free-form and rule-based). This means that computer games which invite make-believe activity – like *The Sims* – can be described as narratives regardless of strong ludic elements. However, Ryan ultimately does not cross fully into the new territory of interactive video game narrative, as she stays convinced that "interactivity is not a feature that facilitates the construction of narrative meaning" (Ryan 2006).

Crossing Ryan's border, other scholars have worked to understand interactive forms of narration and to further develop the analytical arsenal. For the sake of space, the following section can only provide a rough overview of this work and does not claim to be extensive. Additional material can be found for example in the proceedings of the ICIDS (https://link.springer.com/conference/icids) and AIIDE (https://dl.acm.org/results.cfm?query=AIIDE) conferences as well as the INT (http://www.di.unito.it/~rossana/INT10) workshop.

For example, drawing on traditions in semiotics along with poststructuralist and pragmatist narrative theories, Gabriele Ferri (2007a, b, 2013, 2015) develops an "epistemological common ground" (Ferri 2015) to support a multidisciplinary analysis of video game narratives and other forms of interactive digital narratives (IDN). In particular, Ferri tackles the issue of textuality under interactive conditions and provides a model ("interactive matrix") for the encounter of player and computational system.

In 2011, Clara Fernandez-Vara also applies a semiotic perspective – based on Peirce (1992) – to pick up Jenkin's thread of *embedded* narrative (Jenkins 2004) and further develop it as "indexical storytelling" (Fernández-Vara 2011) (in the Peircian sense of indexical signs) through meaningful objects, encounters, and traces left by other players.

In 2001, Michael Mateas develops a poetics for interactive drama (Mateas 2001) extending Brenda Laurel's earlier work (Laurel 1991) in connection to Murray's affordances and aesthetic qualities (Murray 1997) as a theoretical basis for this later narrative artificial intelligence (AI) projects. Mateas' perspective is referenced by Frasca's (2003b), but little further discussion occurred.

Working on narrative in the related field of virtual environments, Ruth Aylett develops a theoretical position on emergent narrative and the problem of the "narrative paradox" (Aylett 2000) (also see the related article on "Narrative Designer's Dilemma" in the cross-references section below) – the conflict between narrative coherence and interactor control. In 2003, Ruth Aylett and Sandy Louchart published a "Narrative Theory of Virtual Reality," which explicitly treats as VR as a narrative medium (Aylett and Louchart 2003). Later, they collaborate on extending narrative theory to cover emergent narrative in AI-based experiences and video games (Louchart and Aylett 2004).

In addition to Aylett, Louchart, and Mateas, a range of additional AI researchers have developed analytical perspectives on narrative alongside their work in applying AI to various forms of IDN (Cavazza et al. 2008; Cavazza and Pizzi 2006; Cavazza and Charles 2002; Riedl 2010; Riedl and Bulitko 2012; Riedl and Young 2006; Bates 1993; Mateas and Stern 2005; McCoy et al. 2009; Saillenfest and Dessalles 2014)).

Design-Based Perspectives

The perspective of game developers towards "narrative" has been described as "pragmatic" (Ryan 2006) in its flexible application of various narrative models and concrete design methods to create video game narrative. The available literature is focused on a traditional understanding of narrative, influenced by cinematic approaches and screenwriting (Field 1979) and prominently features concepts like the "Hero's Journey" (Campbell 1949) (applied for example in Ernest Adams's *Fundamentals of Game Design* (Adams 2010)) or the "story arc." In her book *Game Design Workshop* Tracy Fullerton writes: "[. . .] the tension in a story gets worse before it gets better, resulting in a classic dramatic arc [. . .] This arc is the backbone of all dramatic media, including games" (Fullerton et al. 2008). This traditional understanding of narrative is foregrounded also in an opinionated column in the same book by game designer Jesse Schell, author of another influential book on game design (Schell 2008). In particular, Schell denounces the idea that the interactive aspect of games have a fundamental influence on narrative: "The idea that the mechanics of traditional storytelling, which are innate to the human ability to communicate, are somehow nullified by interactivity is absurd." (Fullerton et al. 2008) A critique of Schell's perspective can start with the realization that his notion of "traditional storytelling" is based on a narrow, colonial perspective of narrative that ignores many non-European varieties (cf. (Madej 2008)) with very different mechanics, for example, multiclimactic, cyclical African oral storytelling forms (Jennings 1996), Asian structures that lack a tension arc (Kishotenketsu) (Koenitz 2016), or forms of participatory theater like Arturo Boal's "Theatre of the Oppressed" (Frasca 2001). Schell's assertion is therefore untenable and points again to the fundamental problem of totalizing and implicit assumptions (in Schell's case that of a universal "mechanic of traditional storytelling") in the discourse about video game narrative.

During the Narratology vs. Ludology debate, Celia Pearce argues for a relocation of narrative in video games as an element of the player experience. She develops a set of categories to describe narrative aspects: *Experiential, Performative, Augmentary, Descriptive, Metastory,* and *Story System* (Pearce 2004). For her, the *Experiential* aspect always exists, while the other ones depend on the specific implementation in a particular artifact. Pearce' foray into the experiential dimension is significant, as she opens up a productive avenue to analyze video game narratives. However, her framework carries the danger of understanding all in-game experience as narrative. Conversely as Calleja reminds us (2013) referencing Aarseth (2004) if everything is narrative, nothing is.

The experiential perspective is also a cornerstone of Salen and Zimmerman's game design book *Rules of Play*. They write: "our intention is not just to arrive at a formal understanding of narrative (What are the elements of a story?) but instead an experiential one (How do the elements of a story engender a meaningful experience?)" (Salen and Zimmerman 2004). For these authors, the main question is how to best design "narrative play" (ibid). A decade later, Teun Dubbelman makes this perspective even more concrete in his analysis of "Narrative game mechanics" (Dubbelman 2016).

Specific Approaches

Instead of defining video game narrative within the framework of traditional narratological analysis and forms, Calleja (2013, 2015) and Koenitz (2015, 2010b) argue for the development of a specific theory of video game narrative (for Koenitz as part of a wider understanding of interactive digital narrative (IDN) phenomena like interactive documentaries, electronic literature, artistic installations). Calleja contends that the lack of progress in understanding video game narrative is due to the overly reliance on "classical notions of narrative developed for non-ergodic media such as film or literature" (Calleja 2013). He therefore calls for a re-conceptualization of narrative that takes into account "the cybernetic nature of games and thus factor in the experiential

dimension of the human as well as the formal properties of the game." (ibid). Conversely, Koenitz references Roy Ascott's theory of cybernetic art (Ascott 1968, 1967, 1964) as a basis for his SPP model (System, Process, Product) (Koenitz 2015, 2010b). The triad of System – Process – Product (digital artifact, user interaction and resulting output) bridges the gap between artifact and instantiated narrative (cf. Montfort (2005)). By understanding the content of the system as a "protostory," the narratological category of "story" is relocated with particular instantiations (products), while the analysis of the process (as userly performance (cf. Knoller (2012))) can be given proper analytical space.

Natural Walking in Virtual Reality

Niels Christian Nilsson
Aalborg University Copenhagen, Copenhagen, Denmark

Synonyms

3D user interfaces; Virtual locomotion; Virtual travel

Definition

Travel, or locomotion, is a fundamental and universal task within virtual reality (VR). However, enabling users to freely walk through virtual environments (VE) poses a considerable problem when the VE is larger than the tracked physical space.

Introduction

To most people, the act of moving from one place to another (i.e., locomotion or travel) is a common everyday activity. Similarly, locomotion is a fundamental and universal task within virtual reality (VR). Yet allowing users to freely navigate virtual environments (VEs) on foot is anything but a trivial challenge with respect to virtual reality. In the VE the user's movement should only be constrained by the virtual topography and architecture. However, in reality the user's physical movement will always be limited by the size of the tracking space.

Locomotion Techniques for Virtual Walking

The literature on virtual walking describes numerous locomotion techniques intended to facilitate unconstrained walking in virtual worlds that are larger than the tracked physical space. These techniques may be broadly divided into three categories:

Repositioning systems are designed to ensure that users remain relatively stationary by canceling out their forward movement. Examples of virtual locomotion devices include linear and omnidirectional treadmills (Feasel et al. 2011), motorized floor tiles (Iwata et al. 2005), cancellation of steps using strings Iwata et al. (2007), a human-sized hamster ball (Medina et al. 2008), and friction-free platforms Swapp et al. (2010).

The second category, *gesture-based locomotion*, comprises techniques requiring users to perform a gesture serving as a proxy for actual steps. So-called walking in place (WIP) techniques are a common gesture-based approach where virtual movement is generated from on the spot stepping-like movements (Nilsson et al. 2013a; Slater et al. 1993; Wendt et al. 2010, for example). Alternative gestures include, but are not limited to, arm-swinging (Nilsson et al. 2013b), head swaying (Terziman et al. 2010), shoulder rotation (Guy et al. 2015), and hip sways (Nilsson et al. 2013b).

The final category *redirected walking* manipulates the physical transformations of the user's movement within the virtual environment so that motion is no longer mapped 1:1 (Razzaque et al. 2001; Suma et al. 2012a), or manipulates the characteristics of the VE (Suma et al. 2011, 2012b). These manipulations make it possible to guide the physical path of walking users to travel through virtual environments that are larger than the physical space.

Conclusion

Most of the techniques belonging to these three categories have their merits. However, they come with unique benefits and limitations. While repositioning systems can confine the user's movement to an area of limited size, most current implementations are relatively cumbersome and expensive. Gesture-based locomotion offers an inexpensive and convenient alternative. However, the absence of actual steps enables only partial proprioceptive and kinesthetic feedback. Moreover, repositioning systems and gesture-based locomotion are designed to limit translational movement and therefore limit vestibular self-motion information. Redirection techniques involve actual walking which constitutes a considerable advantage. However, most redirection techniques demand a large physical walking space in order to be deployed without detection. Natural walking in VR remains an active area of research where existing techniques continuously are being refined and new techniques regularly are proposed. For a comprehensive overview of this body of work, see the book *Human Walking in Virtual Environments* (Steinicke et al. 2013).

Navigation Artificial Intelligence

Fabien Gravot
SQUARE-ENIX, Tokyo, Japan

Synonyms

AI Motion; Locomotion; Path planning; Steering

Definition

Navigation is the set of processes used to guide the movement of an artificial intelligence (AI)-controlled agent. It is generally divided into three phases: path planning, to find a path through a static environment; path smoothing, to avoid unnatural motion; and steering, to compute the current velocity needed to follow this path while avoiding other agents.

Introduction

Navigating an AI in a game is a classic AI application. It was the first type of AI system to be created as middleware and represents one of the biggest reusable parts of most games, mostly because of the complexity and robustness needed to complete this task. Within a large game world, it is not possible to edit the navigation data by

hand. Automatic generation must therefore be used and be robust enough to cope with a wide range of worlds.

Moreover, AI navigation is a critical system: an error will create an obvious bug like an agent turning in a circle indefinitely or going in the wrong direction. More difficult problems arise with crowds, where deadlock problems can occur. Such problems will break the immersion of the game. Even a simple animal such as a mouse is able to find its path; this fundamental functionality has been acquired over millions of years of evolution and is so basic to human beings that an error in navigation is not forgivable for the AI.

Because local navigation methods can become trapped in local minima, a proper solution would be to use a search algorithm. We hence first focus on how to represent the navigation data and how to find a path for a single agent. Then, we briefly mention a method for smoothing this result and how to coordinate the motion of different agents.

Path Planning

The goal of pathfinding is to ensure that an AI can move in an environment without becoming stuck in a local minimum. For instance, in Fig. 1, the agent should not travel directly toward its target on the left, but follow the obviously correct path by first going right. Even if a local method can work well in some environments (e.g., outer space populated with small meteoroids), local methods often become trapped in local minima or yield unrealistic motion (i.e., they follow a wall on one side to escape a labyrinth) for an agent that moves inside a well-known environment.

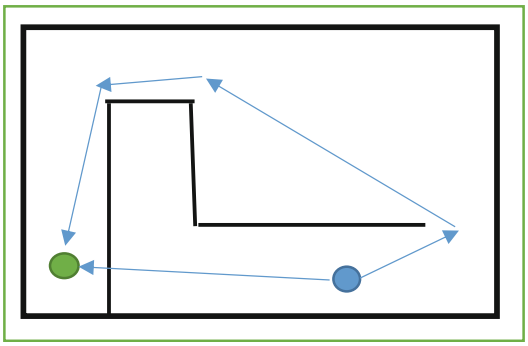
Pathfinding is a search algorithm to find the shortest path inside a navigation graph. This section first describes commonly used navigation data, and then the pathfinding algorithm A∗ is briefly presented followed by several of its optimizations.

Navigation Data

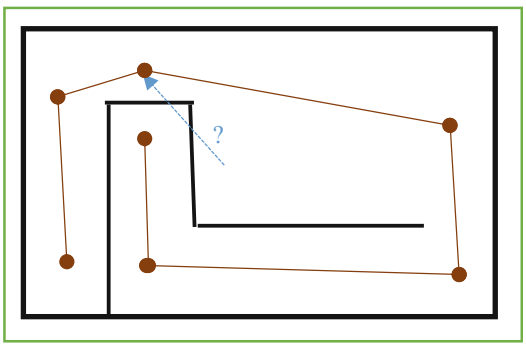
Before even considering how to look for a path, a suitable data representation should be determined. It is in fact not efficient to use direct collision data: a much lighter model should be used, as described below.

Waypoints

In computer science, the waypoint system is one of the oldest navigation representation systems for the pathfinding task. This system consists of a graph node in which the edges represent possible motions between points (nodes). Figure 2 shows an example of such graph. The main problem with such a graph is a lack of information about the paths not defined by the graph edges. That is, we do not know if it is safe to move outside this graph. It is still a very easy and natural way to set up navigation and can be combined with other



Navigation Artificial Intelligence, Fig. 1 Example of pathfinding. The path in front of the agent is a dead end. First, the agent must make a detour to reach its target



Navigation Artificial Intelligence, Fig. 2 Waypoint graph for locomotion. Note that once the agent moves off of the edges, there is no guarantee it will be able to reach the next node

methods described below to either give a designer the ability to edit the preferred route for crowd flow (Bernard 2008) or generate a more abstract hierarchical graph on top of another method to speed up pathfinding over long distances (Gravot et al. 2013; Alain 2018).

Grids

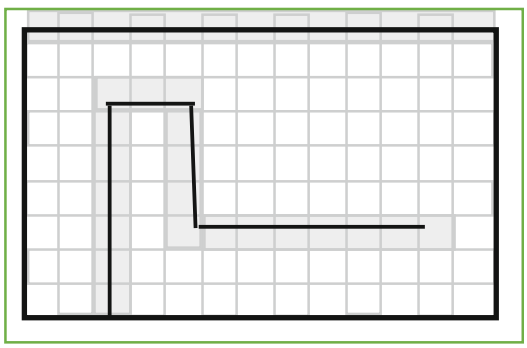
The grid system stores a world's connectivity inside a two-dimensional (2D) grid. This can be very efficient if the game design matches this representation. It was also the first system to enable some version of automatic generation. Because each cell is the same size, it is possible to use a flow field to compute the desired motion in each cell in one pass. This method is very convenient for crowd motion when all agents have the same goal (Mika and Jack 2013; McCarthy 2017). The main drawbacks are the memory cost and the number of nodes that must be explored to find a path. In contrast to the waypoint system, the grid system (Fig. 3) provides connectivity information for the entire space, allowing an agent to move freely within the world.

Navigation Mesh

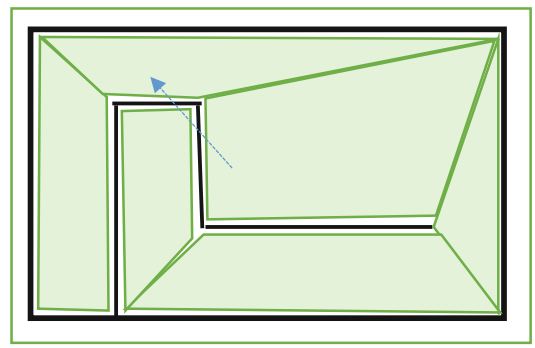
To be able to scale up the navigation system to a large world, instead of grid, it is possible to use a mesh composed of convex polygons (Fig. 4). The graph is then represented using polygons as nodes and adjacent polygon edges as graph edges. Since Miles (2006) and the release of the MIT-licensed Recast Navigation toolset (https://github.com/recastnavigation/recastnavigation), the automatic generation of such meshes from collision data has become widespread. Now, a large amount of middleware exists to create such data (e.g., Recast, Havok AI, PathEngine, and NavPower). The original version is based on collision voxelization and is able to scale well with complex geometry, whereas new methods are based on geometric construction and can increase the precision of the resulting mesh (Havok AI, PathEngine). Similar to a grid system, a navigation mesh can cover all possible navigation data, but with far fewer nodes and hence faster pathfinding. It is also easier to support overlapping floors with connected slopes. This is the most commonly used navigation data for 2D locomotion in modern games. However, because nodes have different sizes, it is difficult to use a flow field and more tactical reasoning. For this task, waypoints, a grid, or a tactical point system can be used (Mika and Jack 2013).

Sparse Voxel Octree

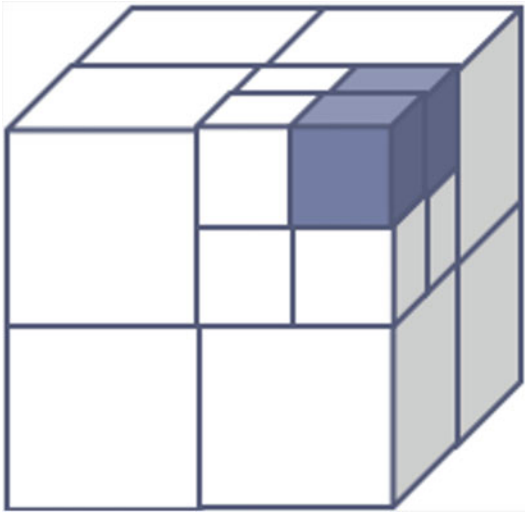
For 3D navigation, the 2D representations presented above may not be sufficient. The waypoint system can still be used, but to have real freedom of motion, an auto-generation method is needed. Similar to the grid system, a sparse voxel octree can be used (Fig. 5). For 3D navigation, there is often a large amount of free space in the world, and using a sparse representation can help reduce the data size. However, the size of the data and the



Navigation Artificial Intelligence, Fig. 3 Grid system for locomotion



Navigation Artificial Intelligence, Fig. 4 Navigation mesh for locomotion. With this representation, it is possible to find a path anywhere within the navigable area



Navigation Artificial Intelligence, Fig. 5 Sparse voxel octree for 3D locomotion. Each node can be split into eight smaller notes if there is a collision

pathfinding cost associated with it are still an extremely complex problem (Brewer 2017).

A∗ Algorithm

All pathfinding algorithms are essentially based on the A∗ algorithm (Hart et al. 1968). The only possible exception is when it is necessary to know the best path between any two nodes in the graph, in which case, the Floyd–Warshall algorithm is best (Cormen et al. 1990). However, even in this case, A∗ may be a better choice (Gravot et al. 2013) if paths over long distances do not require the best solution.

A∗ will find the optimal path within a weighted graph (such as the ones presented above), i.e., it will find the path with the lowest cost. For that, it uses a heuristic H(n) to estimate the remaining distance to the goal. As shown in the code below, the algorithm expands first nodes with the lowest total cost F(n), which is the sum of G (n) (the cost to reach that node) and the heuristic H(n).

For a consistent heuristic H(a) > = d(a, b) + H (b), A∗ can expand each node only once. Note that each node has only one parent. If the heuristic is consistent (i.e., its value is always lower or equal to the cost to reach the goal), the algorithm will return the best possible path. Note that some games use inconsistent heuristics to speed up the search process.

```
open_set := { start }
closed_set := {}
While not empty open_set:
    current := node in open_set with the
             smallest total cost F
     If current = goal
         Return path from goal to start
     open_set.remove(current)
     closest_set.Add(current)
     for each neighbor of current
         if neighbor in closest_set
             continue
         score = G(current)
                 + d(current, neighbor)
         if neighbor not in open_set
             open_set.Add(neighbor)
         else if score >= G(neighbor)
             continue
         neighbor.SetParent(current)
         G(neighbor) := score
         F(neighbor) := score
                 + H(neighbor)
```

Code 1: A∗ algorithm

Pathfinding Optimization

Pathfinding is still a costly task, and it is often a good idea to do some time slicing on it (at least to split the pathfinding requests on several frames). Most often it seems natural to have a small delay for reaction time so such time slicing will integrate well. Nevertheless, reducing processing for pathfinding can be needed even for one request. The first step can be to look at the navigation data. The less nodes to expend, the faster it will be. For similar precision, the navigation mesh will have less nodes than the grid, but with one more dimension, sparse voxel octree can be very costly. The other way can be to use one of the following optimizations.

Connectivity

One problem with A∗ occurs when there is no path. A∗ will then explore the entire connected space before returning false (to indicate there is no path). One possible solution is to tag a connected part of the environment and check for tag equality. When there are agents with different traversal capabilities, this will still result into a

graph search, but with far fewer nodes, and it is likely that results will be cached for the most common patterns. For dynamic environments or very large worlds, a hierarchical approach can be used (Gravot et al. 2013; Alain 2018) to reduce the update cost. In fact, a simple path added or removed may imply changing the tags of many data, but a hierarchical update strategy is a good way to reduce this cost. In that case the connectivity update computation complexity is O(log(n)) in the number of navigation data nodes. In practice the update algorithm is generally very light compared to the generation of new navigation data which triggers it.

Bidirectional A∗

Even if the start and the goal can be connected together, A∗ can explore many nodes before reaching the goal. Bidirectional A∗ has made recent progress (Sturtevant 2018) toward reducing the number of nodes that must be searched and never searches path that costs more than twice the optimal path. Even if it is slower than A∗ in many cases, it still avoids the worst cases of A∗.

Goal Bounding

This optimization precomputes the bounding volume of all the points for which the graph edge is the optimum one Rabin and Sturtevant (2017). Because this optimization can be performed on any type of navigation data, it is a very convenient way to speed up an algorithm. Then, at run-time, only edges that have a bounding volume that includes the goal need to be expended. However, this approach cannot be applied to dynamic navigation data. Precomputing the constraint is $O(n^2 \log(n))$ in the number of navigation data nodes.

Jump Point Links

This optimization results in a big speedup on grids with uniform weights (Harabor and Grastien 2011; Sturtevant and Rabin 2017). Moreover, it works without any preprocessing (although speedup can be obtained even with preprocessing). It works by using a set of rules to do a type of raycast, effectively exploring one direction until it reaches an obstacle. This algorithm uses the symmetry property of the grid representation and these raycast tests to reduce the number of nodes that need to be explored.

Experiments on *StartCraft*, *Warcraft III*, and *Dragon Age* maps have shown a speedup of more than 100 times with JPS+ (JPS with preprocessing) and more than 1000 times if also combined with Goal Bounding (Sturtevant and Rabin 2017).

Precomputed Paths

Precomputed paths can be used to speed up the search algorithm (Gravot et al. 2013) or to ensure consistent paths across the network (Cournoyer and Fortier 2015). This can also be a good way for optimizations based on level of detail (LOD) and crowds to share valid paths among agents. On one hand (Gravot et al. 2013), it is possible to precompute all possible paths and have a hierarchical lookup table to cope with the memory explosion problem. On the other hand (Cournoyer and Fortier 2015), we can precompute paths between waypoints and then generate a high-level waypoint graph with very few nodes and complex paths between them. In both cases the search space can be greatly reduced.

Hierarchical Planning

Hierarchical planning substantially reduces the search cost with losing the optimality where it does not matter, i.e., far from the start and goal (Gravot et al. 2013; Alain 2018). Within very dynamic environments where pathfinding is requested often, having an algorithm that is fast and precise near the start can make the AI move locally optimally without falling into local minima and becoming unable to reach the goal.

Such methods are normally based on node connectivity, and high-level paths can have a coarse estimation of the distance and bigger nodes.

Hierarchical planning can also be used for LOD. For very large worlds, all the navigation data cannot fit into the memory, but we would still like for the AIs to exist and travel on a path even when they are far from the player. An abstract waypoint graph can be used for long-

term pathfinding and can reside in memory for agent simulation (Lefebvre 2018).

Path Smoothing

Once a path has been found, it is generally not directly usable. This is especially true for dense representations like grids or navigation meshes. Even if a straight path exists, the path planner explores the graph's edges, which are not necessarily aligned with this path. The resulting path has often zigzags. Moreover, the planner often does not consider the kinematic constraints of the agent. It is often desirable to create a path able to respect them and to use the constraints to control the agent on this smoothed path, for instance, by slowing down before a sharp turn.

There are several example algorithms for dealing with these two problems.

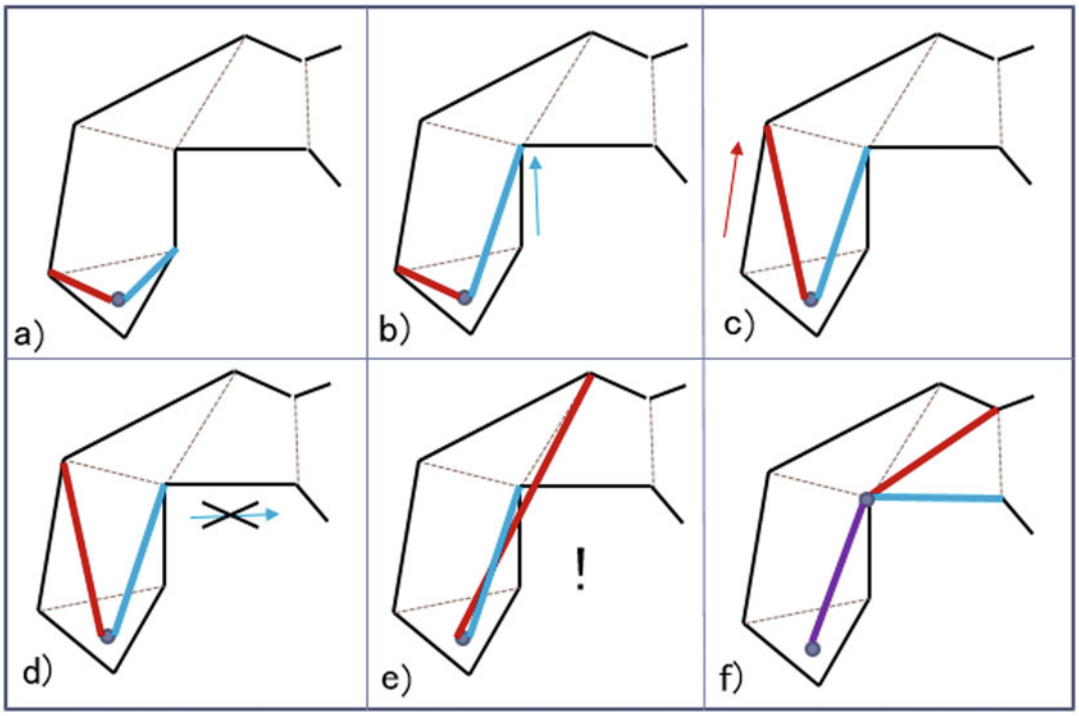
Funnel Algorithm

The funnel algorithm (Demyen 2007) is a very common path smoothing algorithm, especially for navigation meshes. In this case, the pathfinding determines a polygon path with a cost based on edge centers. However, a path through edge centers is far from optimal. Because we in fact have a path composed of polygons, any path going through them is valid. The funnel algorithm (Fig. 6) can find the shortest path within a polygon path.

The main drawback of the funnel algorithm is that it does not explore outside the channel. However, it can also be used for finding a first path before other algorithms are used.

Path Cut

The path cut algorithm is the simplest path smoothing algorithm. Two points on the path are chosen, and it is determined whether a straight-line path between would be valid (i.e., a



Navigation Artificial Intelligence, Fig. 6 Example of using the funnel algorithm to smooth a polygon path. (**a**) Start the funnel by expanding it. (**b**, **c**) The left side can only expand to the right and vice versa. (**d**) The right side cannot be updated. (**e**) The left side would cross the right one if it were updated. (**f**) A new waypoint is created in and a new funnel can start

navigation raycast check). If this is the case, the intermediate path is replaced with this line. This can be a costly algorithm, but after applying the funnel algorithm, the number of points that must be considered can be reduced.

Regardless, it is always advisable, even before finding a path, to use a navigation raycast to determine if the start and goal can be reached using a straight line.

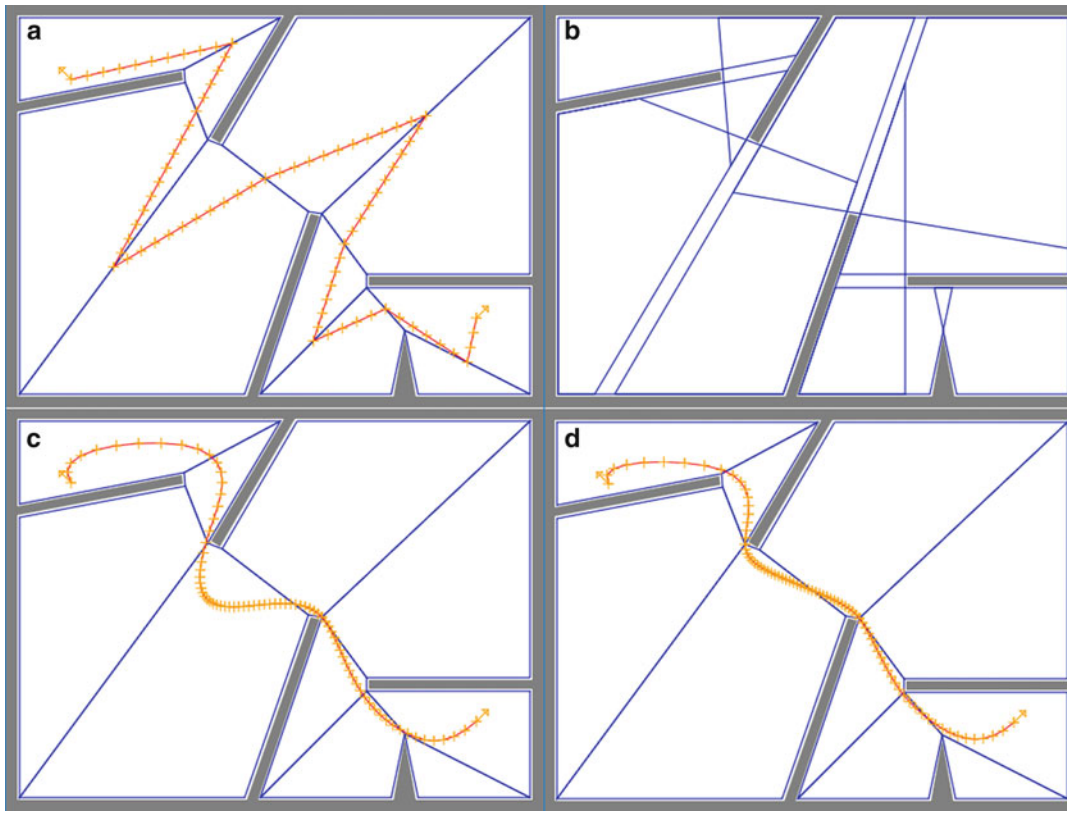
Adding Smoothing Constraints

Once we have the shortest path as a series of straight lines, it may be necessary to smooth it to respect the kinematics of the agent using it. Several methods can do this, but the best method to use will also depend on the complexity of the kinematic constraints. Bezier curves yield aesthetically pleasing but physically unrealistic motion. Circles ensure the continuity of the speed vector (but not the acceleration vector), and cycloids are curves used by road traffic planners, but are more complex to compute. The goal here is to add a smooth transition in place of each segment-to-segment transition.

To be complete, the algorithm must also check for possible collisions with the new curve. When collision occurs, sharper versions of the path with lower speeds can be used.

Path Optimization

Another solution to smoothing a path is convex optimization (Langerak 2017). The original path is sampled and each sample is associated with a convex volume on the path. The original method (Langerak 2017) was based on circles, but this can



Navigation Artificial Intelligence, Fig. 7 Example of path optimization above a navigation path. (**a**) Original unsmoothed path with the desired orientation at the start and end. (**b**) The main convex polygons used to constrain the path point locations. (**c**) Smoothed path. (**d**) Another smoothed path resulting from different smoothing parameters

also work with polygons built over the polygon path, as shown in Fig. 7. Just as for the funnel algorithm, this approach works only with valid path edges. Because it is an optimization problem, it is costlier than the other algorithms, but ensures path validity.

Steering

Once a path is found, the agent must follow it, but generally, it is not the only one in a world. It must hence coordinate itself with other agents. This is the goal of the steering algorithm. Most steering algorithms consist of three phases: computation of the desired velocity for following the path (or the current desired action); avoidance, which adapts the velocity to avoid other agents; and post-processing, which is used to create a more realistic model.

Desired Speed

Computing the desired speed is the first step of steering. Sometimes, for crowd simulation, a flow field is used to determine a desired speed on each point of the map. Sometimes the steering behavior of flocking agents, such as when fleeing a threat, can be used. This can be as simple as a direct vector-based computation (Reynolds 1999) or involve a tactical point system to find a goal with various conditions and avoid local minima (Johnson 2017).

When an agent is following a path, a part of the path smoothing can in fact be done here (Guðmundsson et al. 2017). For a dynamic world, there is no need to smooth too much ahead (unless it is a straight line), and adding the agent's kinematic constraints can help yield various types of desired motion. Path smoothing is still useful for finding the portals with transition points that need to be passed. This information can be used for detecting the next desired direction. Note that it is not good to attempt to move toward the waypoints themselves, as this can create artificial congestion. A path generally provides margins from which the portal can be defined. This enables the agent to keep some freedom for steering.

Avoidance

Avoidance is generally the core and the most expensive part of the steering algorithm. There are three types of avoidance algorithms:

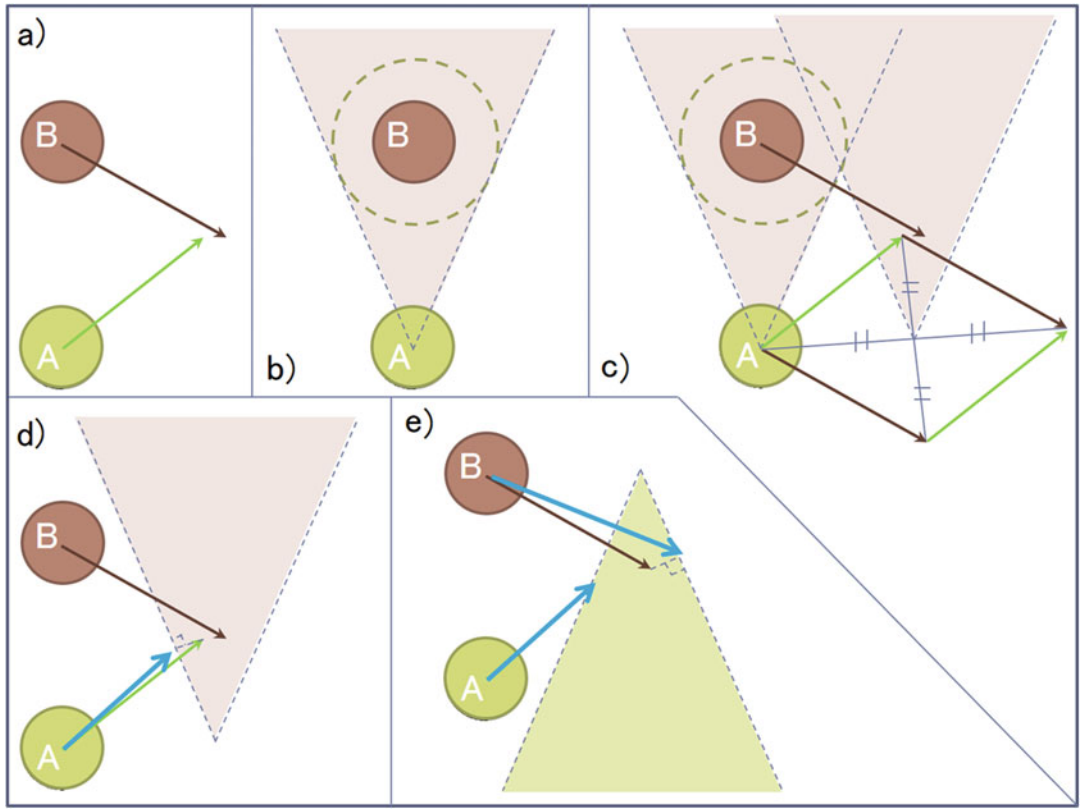
- Empiric algorithms, such as the Boids or Reynolds separation forces (Reynolds 1999) algorithms
- Robotic algorithms, such as reciprocal velocity obstacles (RVO; van den Berg et al. 2008) or the optimal reciprocal collision avoidance (ORCA; van den Berg et al. 2011.
- Sociological algorithms, such as the human-like (Guzzi et al. 2013) or force-based (Guy and Karamouzas 2015) algorithms

The empirical algorithms arise from simple experiences and the game industry. They are fast and tunable, although too much tuning may be required. The robotic algorithms give proof for no collision within a set of assumptions: notably perception and holonomic motion. As shown in Fig. 8, RVO computes the possible velocity in a set of constrained polygons in velocity space. ORCA is much faster because it uses a plan (but also removes possible solutions). These two algorithms generally form the default implementation of most navigation middleware. Even if the original assumptions are not respected, they still can yield good results. Note that tuning them is not necessarily straightforward (Sunshine-Hill 2017).

Social-based algorithms are based on measures of human crowd behavior and try to simulate similar behaviors. They have possible failure cases but yield results that may be more realistic. Moreover, their model is often closer to the ones used in games and may results in fewer approximations. Compared to agents following ORCA and RVO, agents following social-based algorithms more often force their way out of than run away from a crowd approaching on the other side, which is generally more realistic.

Connection with the Animation and Physics Systems

Most avoidance systems use a simplified model to compute avoidance. Hence, it is often necessary



Navigation Artificial Intelligence, Fig. 8 RVO algorithm. (**a**) Agents and their desired velocity. (**b**) The velocity obstacle of B toward A, computed by adding the radius of agent A to that of B. (**c**) Velocity obstacle projected into velocity space by sharing half of the responsibility of avoidance (the mean of the speeds of A and B). (**d**) Nearest valid velocity for A computed from the original desired velocity. (**e**) Nearest valid velocity for B is computed to obtain the two corrected velocities that avoid collision

to perform some temporal smoothing. For instance, a steering algorithm can use a wide range of speeds, but the agent may not have very slow motion animation. Low speed must often be dealt with properly.

Another important point is that collisions may still occur. It is still realistic or even desirable to have collisions in edge cases. Because an avoidance system can predict collision in advance, it is even possible to begin avoidance animation to make the collision look good.

Moving on Rails

There is one notable exception to the three-step system presented above: the navigation system of *Hitman: Absolution* (Anguelov et al. 2012). When more time is spent on path smoothing and preprocessing, it is more wasteful to perform steering avoidance. Moreover, steering always uses a simplified model, and the motion quality may decrease as a result. In *Hitman: Absolution*, the designers chose to show the agent's path to the player, and this one must not change.

It is possible to keep the path and coordinate the speed of the agent to avoid collision. For a deadlock on a narrow corridor, additional coordinate planning is possible (i.e., to make one agent allow another to pass by).

Conclusion and Discussion

This entry has briefly introduced many algorithms that can be used for the different steps of a

navigation AI. The goal is to enable agents to avoid local minima and find their path in a complex environment. Something that most animals are able to do naturally is still a complex problem for an AI, and it must be accomplished robustly. Methods continue to be proposed to either improve the quality or support dynamic environments within the time budget imposed. Note that using a processing queue, it is possible to time-slice the planning work while retaining more than enough reactivity.

The navigation AI was one of the first AIs to be used as middleware; the complexity and robustness of the navigation task justified such investment. Moreover, it was shown in this entry that it is possible to create increasingly more specialized awareness behavior. Not only paths, jumps, and vaults, but tactical decisions and other influence maps can be added to an AI navigation system.

NBA – National Basketball Association, a professional basketball league in North America
NBA 2K – A series of basketball sports simulation video games

Introduction

NBA 2K is a series of basketball sports simulation games developed by Visual Concepts and published by 2K Sports annually. It is based on the National Basketball Association and recently the Women's National Basketball Association as well. NBA would have yearly releases after its initial release in 1999 (Justice 1999). The cover for the game each year would feature a player in the NBA who was dominant or influential. See Table 1 for the list of players featured on the various covers.

NBA 2Ks was originally published by Sega Sports with the first release on the Dreamcast in 1999.

NBA 2K2 was the third installment in the NBA 2K series released on the Dreamcast, GameCube, Xbox, and the PlayStation 2 with Iverson returning on the cover. NBA 2K2 was the last 2K to be published on the Dreamcast.

NBA 2K, a Brief History, Table 1 List of players featured on the NBA cover

2K Game	Player(s) on Cover
NBA 2K	Allen Iverson
NBA 2K1	Allen Iverson
NBA 2K2	Allen Iverson
NBA 2K3	Allen Iverson
ESPN NBA Basketball (2K4)	Allen Iverson
NBA 2K5	Ben Wallace
NBA 2K6	Shaquille O'Neal
NBA 2K7	Shaquille O'Neal
NBA 2K8	Chris Paul
NBA 2K9	Kevin Garnett
NBA 2K10	Kobe Bryant
NBA 2K11	Michael Jordan
NBA 2K12	Magic Johnson, Larry Bird, Michael Jordan
NBA 2K13	Blake Griffin, Kevin Durant, Derrick Rose
NBA 2K14	Lebron James
NBA 2K15	Kevin Durant
NBA 2K16	Stephen Curry, James Harden, Anthony Davis, Michael Jordan, Pau Gasol, Marc Gasol, Dennis Schroder, Tony Parker
NBA 2K17	Paul George, Kobe Bryant, Danilo Gallinari, Pau Gasol
NBA 2K18	Kyrie Irving
NBA 2K19	Lebron James
NBA 2K20	Anthony Davis
NBA 2K21	Damian Lillard
NBA 2K22	Luka Doncic
NBA 2K23	Devin Booker

In 2003, the fifth installment was ESPN NBA Basketball. It was released on the Xbox and PlayStation. This was one of the two times when ESPN had their name on a 2K title. This would also be the fifth and last time Iverson graced the NBA cover, making Iverson the only player to get on the 2K over five times and in a row.

In 2004, Sega published the sixth NBA title. NBA 2K in 2005 developed and published their own 2K for the Xbox and PS2 without the need for companies like Sega and EA to help them publish their games.

NBA 2K7 was released on PS2, Xbox 360, and PS3. It was the last 2K on the original Xbox.

NBA 2K8 featured Chris Paul on the cover as well as the Slam Dunk Contest and a legal playlist with 23 tracks.

NBA 2K Online was the next 2K. The game company Tencent brought 2K Online to Asian markets.

NBA 2K10 introduced Kobe Bryant on their cover. It was the game that finally introduced "MyCareer Player." This game mode would go on throughout the rest of 2K.

NBA 2K11 was the legendary 2K with Michael Jordan on the cover. It featured many modes related to Jordan such as the Jordan Challenges. This mode allows players to recreate the most iconic Jordan career moments, such as his 69-point game.

NBA 2K12 was the first 2K to have three different people on their cover: Magic Johnson, Larry Bird, and Michael Jordan. It was also the last 2K to be on the PS2. It implemented an "NBA Greatest" mode where players can choose and play with historic players and teams.

NBA 2K13 was the first 2K to add "MyTeam" focusing on building players' own fantasy team and playing against others online.

NBA 2K14 added Euro League teams and MyPark. MyPark takes their MyCareer player they have used grinded badges for and upgraded his stats so that they can take him to the park and play against other players.

NBA 2K15 added a small feature that allows players to face scan themselves into their MyPlayer so that it looks like they are playing in the NBA.

NBA 2K18 was the first 2K to be released on the Switch. It added different editions for the 2K: The Legend Edition and The Legend Gold Edition. The Neighborhood, another version of MyPark, made its debut in NBA 2K18.

NBA 2K20 was the first 2K to add the 12 WNBAs (Women's National Basketball Association) basketball teams.

NBA 2K MyCareer

MyCareer, a gamemode where players control their own story, was first featured in NBA 2K10 (Santos 2016). Before playing the game, players will be able to choose their build and archetype. Players can choose their height, weight, position, and wingspan. Building MyCareer players is what makes player characters unique before even starting a game. Starting as an upcoming prospect in college, the player's performance will determine when and to what team they will be drafted by in the NBA. Once drafted, they have the ability to improve their role on the team and earn more minutes based off of performance.

The ultimate goal on MyCareer is to achieve all the Hall of Fame requirements and finally retire from the NBA. MyCareer is so popular because players can become an NBA player and play for their favorite team. Even if that team is not any good, they can become their star player and win them a championship, which can be so satisfying with all the hard work they put into it.

NBA 2K MyPark

NBA 2K14 introduced MyPark game mode which became one of 2K biggest modes of all time (SGO Staff Writer 2021). It was not that big in 2K14, but it absolutely blew up in 2K15. It allowed players to take their MyCareer player and play against other real users in pickup style basketball. It offers rewards and a rep system where if players do well in a game they get rep/up. Players will start out as a rookie and go all the way to the destined Legend 3 where they can play as a mascot on the court. It became so

popular that streamers would stream and try to become the first Legend 3 player. It was RedCityBoi who was made famous the entire year.

NBA 2K15 also had different affiliations that were used for years after they were called Sunset Beach, The Old Town Flyers, and the Rivet City Rough Riders. This gave an even more competitive aspect to the game: Other players can come to parks and play against players, but they had to get their rep up to a "Pro 3" rank before players could travel to a rival park. 2K also had a big event where all the affiliations played against each other and whoever won the most would get a brand-new looking park.

NBA 2K15 also added The Stage, which was a more competitive MyPark. Players could also wager their in-game currency, VC, against the other team. If they won, they got it back plus the VC from the other team with a chance to win the jackpot that could go up to 7,000,000 VC. The last big edition that 2K15 had was the Jordan Recreation Center where players could play with any player.

NBA 2K16 was almost the same as 2K15 except that it had a different rep system. Instead of Legend 3, it went all the way to Legend 5. The rewards were cool for Legend 5. If he got a tiger, a tiger would follow him around in MyPark. The first to achieve this goal was DopeSwag who became very popular for the entire year.

NBA 2K17 featured a new mode called Park After Dark with famous DJs, such as DJ Premiere. It was a special night time themed park that was of course played in a night time setting. The basketball courts were highlighted in neon to create the nighttime aesthetic while still being able to play basketball.

NBA 2K LEGEND Reward

The reward before NBA 2K16 was Superstar 5 where players could have a jetpack and fly around the park. Players could also get different badges and stuff for their player. However, the big reward in NBA 2K17 that everyone set out for was LEGEND.

The LEGEND reward was to be immortalized in the next 2K which was NBA 2K18. At first nobody in the community knew what this meant. 2K even kept it silent, but they finally said that there would be a statue in the next 2K for everyone who achieved the goal of a LEGEND. The first person to achieve this goal went by the username OrlandoinChicago. The following 2Ks kept the same rep system and the Neighborhood, but they changed the rewards to be more vibrant.

NBA 2K MyTeam

NBA 2K MyTeam is another game mode that was popular among players (O'Neill 2021). MyTeam is focused on creating a 5v5 team that they can play online or as a single player. Players earn VC for use in obtaining packs or getting a good player for their team. Players can also win rewards on the online mode. For example, players can win a Derrick Rose card if they get to the very end of the Road to the Playoffs, but they must win a perfect game and cannot lose a single time to earn this card. There was also an auction house for cards, but players could not put up cards, they could only sell them. 2K based this auction house on how the players played in a game; if a player played badly, their card would go down; and if they played well, the price would go up.

There are different modes in MyTeam: Blacktop, Domination, and MyTeam Online.

Blacktop is similar to MyPark, but players can pick one of the athletes who are on their team, and they get two random cards. Players could get the two worst cards in the game or the best cards in the game. Then, they would play someone else who did the same thing as them.

Domination is the single player game mode where players pit their teams against other NBA teams. They will win packs for each star. Players need a certain amount of MT (MyTeam Points) to win stars. When collecting all 99 points, players will get a special player for free.

Finally, NBA 2K19 added MyTeam Unlimited with 250,000 tournaments. These tournaments were highly competitive and eventually determined who was the MyTeam champion.

Reception and Controversy

Like every game, there were many controversies among the 2k community. Since there was a new release every year, it often seemed that every game was similar to the one released the previous year with very few changes. Cheating was also a big problem in MyPark and MyTeam. Cheaters would often use a xim, a gaming input adapter that allowed players to make every shot. Microtransactions were also a big controversy among the free to play players. Microtransactions in 2k allowed users to upgrade their player quicker or buy better players in MyTeam. This created a big gap in the game between players who spent money on the game and players who were free to play.

Conclusion

The history of NBA 2K has had its ups and downs throughout the years. Despite strong competitions such as NBA Live (especially in 2008), 2Ks never gave up and the series has become one of the biggest franchises ever. NBA 2K offers popular game modes such as MyTeam and MyPark as well as not so popular modes like MyLeague and MyGM. The simulation game itself is what players have enjoyed for more than 20 years and still remains as the top simulation basketball franchise.

Introduction

New Super Mario Bros. Wii was released in November of 2009 by *Nintendo*. *Nintendo* created the game for the *Nintendo Wii* gaming console, and it was a sequel to the *New Super Mario Bros.* game released in 2006 for *Nintendo DS*. The future iterations of the series include New Super Mario Bros. 2 (2012, Nintendo 3DS) and New Super Mario Bros. U (2012, Wii U). The game follows suit of the other Mario games, having Mario as the main character, with Luigi, Yellow Toad, and Blue Toad available as options for multiplayer mode. The game was first released in North America, Australia, and Europe in November, then in Japan a month later. In the USA, *New Super Mario Bros. Wii* sold 1,390,000 units in November 2009, making it the third best-selling game of the month behind the Xbox 360 and PlayStation 3 versions of *Call of Duty: Modern Warfare 2* (McWherton 2019).

Gameplay and Story

The gameplay for *New Super Mario Brothers* is especially exciting because each level holds its own challenges and rewards. The game is based around eight worlds, not including the secret ninth world that appears after the completion of all the others and the collection of special coins. The game remains interesting due to the fact that each world has a different theme with unique enemies and twists. Within each world, there are somewhere between 10 and 15 levels that must be completed in order to continue. Along the way, there are toad houses that are placed and played solely to give the players rewards and helpful items. In order to complete each level, the player must make it to the end of the level and attach itself to the flagpole to signal completion. At the end of each world, there is a castle with a different Koopaling waiting inside. To complete the castle and unlock the new world, you must defeat the Koopaling for that castle. At the end of the very last castle of the game, Bowser Jr. must then be defeated in order to win the game.

The storyline of the game follows similarly to the original Mario-based games. The replication of the series story in each iteration has been offered as a "audience-targeting strategy" (Smith

2015). Princess Peach is kidnapped from her birthday party by Bowser Jr. and the Koopalings. Mario, and occasionally Luigi and the toads depending on if it is multiplayer or not, spend the rest of the game fighting the enemies at the end of each world in an attempt to save Princess Peach. If the player reaches the end of the game and is able to defeat Bowser Jr., then Peach is released from her cage and saved. Princess Peach and Mario are then able to float away in a hot air balloon together and live peacefully.

This repetition of story where Princess Peach gets kidnapped and victimized has been criticized by Feminist Frequency's seminal video "Damsel in Distress: Part 1 – Tropes vs Women in Video Games" (https://www.youtube.com/watch?v=X6p5AZp7r_Q&list=PLn4ob_5_ttEaA_vc8F3fjzE62esf9yP61) and played a pivotal role in the emerging of #Gamergate Controversy (Burgess and Matamoros-Fernández 2016; Massanari 2017).

Reception

The popularity of the game could also be attributed to the spike in Wii gaming consoles as a whole. "On January 31, 2010, the Wii became the best-selling home video-game console produced by Nintendo, with sales of over 67 million units (surpassing those of the original Nintendo Entertainment System)" ("Wii Sales," 2020). The console became a new, must-have thing at the time. Parents supported it because it offered many family-friendly game options, it was user-friendly for all ages, and it encouraged multiplayer inclusiveness.

Some of the main criticisms of the game were that it felt like a step in the wrong direction as far as the cutting-edge technology. Especially with "new" in the title, many people were expecting a major upgrade in graphics, 3D technology, and more unique gameplay. However, the game was created to fit into the typical Mario Bros. series, so not much was changed in order to preserve the aesthetic. As far as the use of cutting-edge technology, Nintendo purposefully decided to stick with 2D technology and non-HD resolution (Gipp 2019).

Overall, the New Super Mario Brothers game has been played and enjoyed by many throughout the years. It achieved record sales across the world upon release. It is an exciting and well-designed game that has stood the test of time as far as gameplay and inclusion. Some might have wished that Nintendo had utilized more advanced technology at the time, but ultimately the game fits the Super Mario Bros. series well. All in all, it is a must-play if you have not already.

NFT Games

The Revenue Models

Chan Kok Chuen Alvin
Cambridge Corporate University, Lucerne, Switzerland

Synonyms

Blockchain games; Digital collectibles; NFT; Nonfungible tokens

Definition

Nonfungible tokens (NFTs) are blockchain-based virtual assets that have unique information and ID codes that identify them from one another.

NFT games include player interactions, the purchase of avatars and weaponry, and the ability to produce cash from NFT games via the play-to-earn (P2E) model such as the popular game, Axie Infinity.

Introduction

NFT games are those that incorporate NFTs in some way. Unlike other types of NFTs, NFT games include player interactions, the purchase of avatars and weaponry, and the ability to produce cash from NFT games via the play-to-earn (P2E) model such as the popular game, Axie Infinity. In addition, the developers can also write smart contracts that define the rules for the NFTs utilized.

Introduction to NFTs

Nonfungible tokens (NFTs) are blockchain-based virtual assets that have unique information and ID codes that identify them from one another.

People cannot swap NTFs for other assets, unlike cryptocurrencies, which may be easily traded on platforms. That also means that the value of one NFT cannot be the same as the value of the other.

NFTs, also known as digital passports, are digital representations of assets that are linked to the collectors' market.

However, other forms of NFT do exist. The increased interest in NFTs is due in part to their potential economic development and investment possibilities.

Characteristics of NFTs

An NFT must adhere to four fundamental rules:

- It cannot be copied.
- It cannot be imitated.
- It cannot be created on demand.
- It has the same ownership rights and assurances of permanence as Bitcoin.

Each NFT signifies something unique, authentic, and different, similar to collectibles. They have essentially distinct worth and cannot be exchanged (Conti 2021; Nanowerk 2021; BusinessToday 2022).

In the case of digital assets, a creator can additionally receive royalties every time the NFT is sold or exchanged.

Types of NFTs

Artworks

The vast majority of NFTs in use today are works of art – digital arts account for 99% of all NFTs. This is due to the fact that artists were the pioneers to seize and earn from the sale of their digital artworks NFTs. Virtual artworks such as digital photos, GIFs, and short movies are now being sold online as if they were tangible goods. To top it all, such NFTs have been sold for millions of dollars.

Antiques and Collectibles

Collectibles were the first NFTs to be introduced. They are digital versions of tangible artifacts such as Pokémon cards or vintage mint condition toys.

Curio Cards was the first significant NFT collectibles to be released. Since then, other collectibles such as Bored Ape Yacht Club, Cryptopunks, Cat Colony, Meebits, and others have taken off and traded at high prices.

Sports Memorabilia

Sports Memorabilia is one of the most popular NFT categories, with the NBA Top Shot being the most well-known example.

This form of NFT typically contains a video clip of a noteworthy sporting event. The LeBron James Dunk, a video clip showing Lakers star LeBron James dunking the ball, is one of the most well-known NFTS in this category. It was one of the most valuable Sports Memorabilia NFTs ever sold. How much? The NFT video clip was sold for more than $380,000!

Music

Music is also high on the NFT radar. For decades, music has been a fungible product, produced and distributed on records, cassettes, CDs, and digitally. However, musicians and DJs have recently started selling their work as NFTs, making some millions of dollars in a couple of hours.

Due to streaming platform and record label cuts, musicians often only receive a percentage of the royalties generated by their work.

When it comes to NFTs, musicians may retain nearly all of the money, which is why so many are opting to this lucrative option.

Events Tickets

NFTs may also be used as event tickets, making it easier to verify people's tickets and identities. Organizers of major events like concerts and music festivals can use a specific blockchain to create a restricted quantity of NFT tickets. These tickets may be obtained through auction postings and then kept on mobile devices via crypto wallets for simple access.

Real-World Tokens

Many people believe that NFTs will be utilized as real-world tokens in the future. The progress in the NFT area is headed in that direction, and the chances of it becoming a reality are good.

The cryptographic evidence of ownership provided by NFTs allows it to mirror real-world assets. Currently, many NFT initiatives are centered on the tokenization of luxury products and real estate. When you utilize NFT deeds to buy a house or a car, you have additional possibilities.

Domain Names NFT

Domain names are the digital real estate on which our businesses are built. Customers can contact us using a gateway provided by them.

Domain names have never been more precious or significant as they are now. The development of e-commerce in the USA coincides with growing sales of NFTs. This is particularly true for domain names in the NFT business. This digital real estate will become a destination for both NFT buyers and sellers with a memorable NFT domain name.

Furthermore, a domain name has many similarities to NFTs. They are all distinct, nonfungible, and have proved ownership.

What Are NFT Games?

NFT games are those that incorporate NFTs in some way (Cuofano 2021).

Unlike other types of NFTs, NFT games include player interactions, the purchase of avatars and weaponry, and the ability to produce cash from NFT games via the play-to-earn (P2E) model such as the popular game, Axie Infinity.

The allure of NFT gaming is that it generates unique and limited tokens that can be swapped with any other nonfungible token in a decentralized digital ledger based on blockchain technology.

This gives gamers actual ownership by giving them the ability to trade, build, and implement NFTs within a game.

In addition, the developers can also write smart contracts that define the rules for the NFTs utilized.

Popular NFT Games

Axie Infinity

Sky Mavis, a Vietnamese developer, produced Axie Infinity, a Pokémon-style game. It has over 350,000 daily active users, almost 40% of whom are in the Philippines, with Venezuela and the USA being the next two largest markets. The game centers around adorable fuzzy critters known as Axies, which players may breed, acquire, teach, and employ to perform challenges and combat online.

The goal of the game is to collect Smooth Love Potions (SLPs), which can then be used to produce additional Axies to utilize in the game.

SLPs can also be purchased and traded on a cryptocurrency exchange.

Top players are apparently making SLP1,500 (roughly US$435) every day from their Axies.

Alien Worlds

One of the most popular NFT game is Alien Worlds, with over 1.1 million users. This game earns Trilium (TLM), which is used to obtain control in the Planet Decentralized Autonomous Organizations, or Planet DAOs, and to unlock more games.

It replicates economic competitiveness and invites players to run for the planetary council or participate in council candidate elections.

Players in this NFT Metaverse may go on missions and find NFTs, which can subsequently be used to mine Trilium or fight fights and go on missions. NFTs are classified according to their rarity and shininess, which affect their worth in the game.

The Sandbox

The Sandbox is a virtual environment in which users may own and personalize one of the 166 thousand various land pieces. The landowners are allowed to do whatever they want with those land parcels, which are represented as nonfungible tokens on the Ethereum blockchain. They can develop games, virtual museums, or other creative endeavors.

The world of The Sandbox is built with Voxels. From that standpoint, it is extremely comparable to Minecraft. In The Sandbox, however, anybody may create a game, design trendy characters, and earn SAND tokens by fulfilling tasks. Because everyone in The Sandbox contributes to the game's environment, everyone wins benefits. That is what is termed as a earn-to-play revenue model.

Decentraland

The emphasis of Decentraland is on a decentralized economy within the game. The Ethereum blockchain is used to power the crypto game. You can purchase a plot of LAND and begin construction on it.

On these lots, you can build whatever you want. Everything from sculptures and malls to art galleries and movie theaters may be created.

You may either sell or monetize the parcel. A district is formed by a grouping of LANDs with similar themes.

Users in this district can vote to make changes to the district.

The initial auction resulted in the sale of all 90,000 LAND NFTs.

However, you may still purchase them on Decentraland's marketplace with MANA.

Star Atlas

Star Atlas, arguably one of the most anticipated blockchain games ever, is widely expected to set a new standard in the play-to-earn space by combining expansive space exploration gameplay, carefully designed strategy elements, and high-quality graphics to create what could be the first AAA-grade blockchain game.

The game's main focus is on space exploration, mining, and development. Players may design their own personalized ships, crew, and avatars, as well as build up mining operations as they travel around the cosmos. Ships also have warfare capabilities, allowing their owners to participate in PvP and maybe PvE fights for resources and control over various sectors. The majority of in-game assets will be recorded on the blockchain as NFTs and tradeable on the Star Exchange.

Sorare

Sorare is a fantasy football card game that allows players to establish lineups and strategies, making it the ideal NFT game for football fans.

Weekly contests pit participants against other managers using trading cards of professional football players. Like in fantasy football, your points are dependent on real-life events and the performances of the players in your deck.

Cards are classified into four rarity levels: limited, rare, super rare, and unique, which affect their worth on the platform. Players who possess these NFT cards can exchange with other players or sell on the open market for a profit.

NFT Games: The Revenue Models

Play-to-Earn Tokens

Most blockchain NFT games offer an in-game token (money) that can be traded or cashed out for other cryptocurrencies (GOBankingRates 2022). Participants in play-to-earn games are rewarded with digital currency or nonfungible tokens. These blockchain-backed games, also known as P2E, have gone widespread in recent years, becoming a major component of practically every metaverse.

Each platform has its own kind of cryptocurrency to compensate online players for their time investment. Smooth Love Potion, or SLP, is used in the cryptocurrency game Axie Infinity.

For example, it has two purposes:

- It is in-game cash
- An item used to breed characters

When you play Axie Infinity and win fights against Axies (axolotl-type monsters), you are awarded with SLP, which can be trade or cashed out.

Breeding New Tokens

With the introduction of NFT-based games came the breedable NFT.

Breedable NFTs are a fantastic chance for everyone who enjoys online gaming and designing new characters. This is because each platform has its unique breeding regulations. Thus, it is difficult to make broad claims about how breedable NFTs operate in general.

Roaring Leaders, a new NFT collection, for example, permits Roaring Leaders NFTs to be mated and produce Roaring Leaders cubs in a distinct collection.

The company also developed an innovative, Tinder-style dating system that allows Roaring Leaders owners to hunt for a "mate" if they lack both a male and female NFT to breed. Roaring Leaders, like all breedable NFTs, require token payment to be bred. The $ROAR token is used to pay for breeding on this platform.

Minting New Items

Players in metaverse games like as Decentraland and Cryptovoxels may build 3D items, wearables, and other collectibles and earn royalties from secondary sales. Because of smart contracts built on blockchain technology, players in Cryptovoxels can earn up to 10% of a selling price with each subsequent sale.

Players in other games, such as CryptoBlades, may create new weapons and sell them to the CryptoBlades marketplace. Players will be able to submit NFT collectable designs to the upcoming massively multiplayer online RPG (MMORPG) Ember Sword, and, if chosen, will be included to the game, allowing artists to earn royalties on secondary sales in perpetuity.

Staking NFT Game Tokens

NFT staking is the practice of keeping an NFT digital asset on a blockchain and hoping that its value increases over time.

You would be rewarded for keeping your NFT on that specific blockchain. These awards are frequently the protocol's native coin or NFTs.

If you received an NFT from a cryptocurrency game, your ownership would be recorded on a blockchain. An individual can hold on to the NFT and not sell it to anybody else.

The NFT has the potential to grow more valuable (or vice versa) than when you initially received it. As a result, the decentralized financial protocol

would reward you for preserving your proof of stake on its platform. As a result, it differs from NFT trading, in which you try to sell for a profit.

NFT Game Virtual Real Estate

The Sandbox games are decentralized in the sense that players purchase land in the game and can construct anything they want on it.

Minecraft and Roblox are the most popular Sandbox-style games today, with over 175 million users each.

Games like The Sandbox, Decentraland, and Axie Infinity are building the groundwork for players to own a piece of the games they play via NFTs. The blockchain game Decentraland, for example, has transacted over 98,000 ETH in virtual assets.

Another example is the sale of eight pieces of land in the virtual world Axie Infinity for a total of 888 ETH.

Anyone interested in NFT Game Virtual Real Estate Investment?

The right time in now!

Conclusion and Discussion

With three billion gamers expected by 2024, gamers will play an increasingly important role in creating the economics of the digital future. The gaming business is expected to earn $155 billion in revenue by 2020.

Thus, this is one of the most profitable ways to make money with NFT Games (Infostor 2022; Fintelics 2021). That is, if you have the skillset and the ability to attract players with your newly created NFT Game.

Analysts expect that the business will earn more than $260 billion in sales by 2025. This, combined with the growing popularity of NFT collections and NFT gaming, has firms wanting to create their own metaverse or NFT games to help them explore new boundaries in their business models, such as:

- **Increase your exposure and reach:** NFTs are all the rage in the digital economy and have a massive following among millennials. By investing in NFTs and NFT games, you can tap into the interest of a tech-savvy consumer base.
- **Increase revenue:** When an NFT gaming token is traded, developers – depending on the demand for the specific NFT game or in-game NFT – can earn more money.
- **Ownership exclusivity:** NFT games allow its owners to have total control on their assets. This is appealing since it allows gamers to earn cryptocurrency by selling NFTs. Furthermore, tangible ownership provides greater incentives to play a blockchain-based game and can be a consistent source of income.

Nursing Education Through Virtual Reality: Bridging the Gap

M. Mohan
School of Design, University of Petroleum and Energy Studies, Dehradun, Uttarakhand, India

Synonyms

3D simulation; Clinical skills; Healthcare training; Nursing education; Serious games; Virtual reality

Definition

Student nurses gain theoretical knowledge and clinical skills during nursing education; however, there is a gap between what they know and what they can immediately apply in an actual hospital scenario with patients. This can result in serious mistakes with repercussions on patient well-being and satisfaction. Over the years, Mankins and physical simulations have been used by student nurses to practice their skills in a safe environment; however, the advancements in technology have opened up a new paradigm of more realistic and immersive simulations (Hauze et al. 2019; Foronda et al. 2017).

A Manikin is the model of the human body, used for teaching medical or art students.

Virtual Reality (VR) is the use of computer technology to create an interactive three-dimensional (3D) world, which gives users a sense of spatial presence. Serious games are applications with serious purposes, developed using computer game technologies more often associated with entertainment (Ma and Zheng 2011; De Croon et al. 2018).

VR-based games and simulations provide safe environments in which nurses can practice their knowledge and skills repetitively in multiple contexts to reduce the time to competence and risk of failure on the job (O'Connor 2019; Weiss et al. 2018).

This entry touches upon the reasons why virtual reality and game-based approaches have been useful in bridging the gap between theory and practice for nurses.

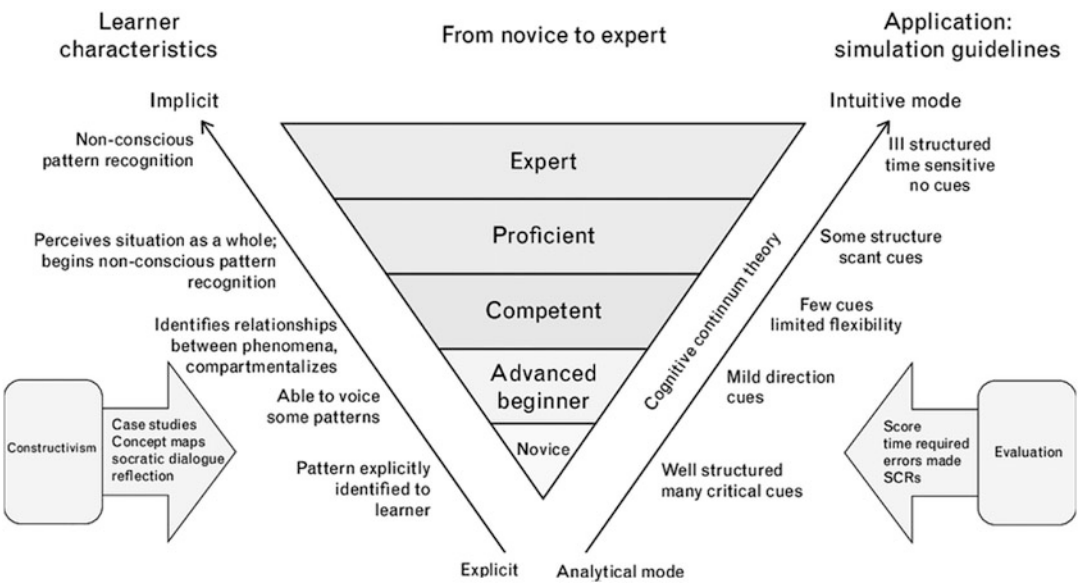
Introduction

Nursing professionals are often challenged to think critically, from simply "knowing," to analyzing and applying knowledge as they go about assessing and implementing patient care, often in high-stress environments. To this end, it is critical to get student nurses to fully understand what is wrong (or right) with the decisions they make and why, in a supervised or simulated environment.

Novel conditions, such as Covid-19 (Barello and Graffigna 2020), demand that healthcare professionals work effectively in situations of ambiguity and high risk. With rising trends toward outpatient care, nurses need to be decisive, communicate effectively, and perform complex problem-solving within a dynamic and changing environment. The global healthcare sector is increasingly turning to virtual reality, simulations, and serious games to create engaging learning experiences for doctors and nurses (Lu 2013). As technologies advance, games can be made more realistic and immersive through VR. The increasing number of affordable headsets such as Google cardboard, oculus go, and HTC Vive in the market and reduced latency factors due to 5G make VR more accessible, safer, and visually appealing. These innovative approaches promise new teaching and learning models that are far more holistic and engaging for the twenty-first-century learner.

Theories and Case Studies

The importance of practice in a real-world environment is proven from the early Constructivist Theory (Cetin-Dindar 2016) to Benner's novice to expert theory (Munjas 1985; Hassani et al. 2017), and Ericsson's concept of deliberate practice (Chee 2014). VR and serious games encourage practice, which helps the learner transition from



Nursing Education Through Virtual Reality: Bridging the Gap, Fig. 1 Benner's novice to expert theory (Hassani et al. 2017)

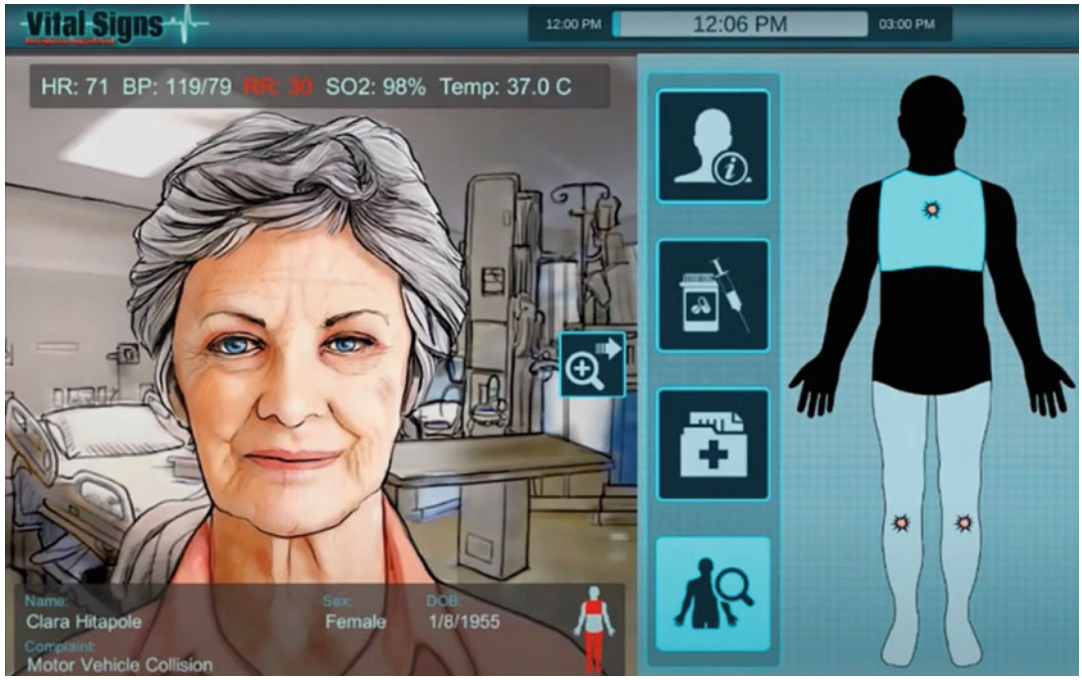
novice to expert, particularly in nursing education by providing learner control and a variety of leveled, realistic scenarios. This is particularly relevant for nurses given the wide variability and high-stakes nature of the tasks nursing professionals need to perform when they transition from a theoretical learning framework to a real hospital context (Fig. 1).

A study of 26 papers concluded that there are four core nursing competencies Serious Games can build among nurses: (1) Procedural skills, (2) Health assessment skills, (3) Communication skills, and (4) Clinical reasoning skills that relate to the core competencies of nursing (Tan et al. 2017). Research also demonstrates educational outcomes related to immersive technology include student learning, confidence, motivation, and engagement (Hauze et al. 2019).

Another research was conducted to understand the perception of nursing students about serious games keeping factors such as interface design, content, and effectiveness (Johnsen et al. 2018). In addition, the study assessed their perspectives on usability and future usage of serious games. A serious game prototype through two simulation courses was administered in nursing education: one for health care at home and one where the context was medico-surgical wards. Teaching clinical reasoning and decision-making skills for nursing students was the main focus of the serious games. Two hundred forty-nine nursing students in their second year took part in the pilot testing phase. There were more students who indicated that the home healthcare simulation course tested their clinical reasoning and decision-making skills. However, the students that played the medical-surgical and home healthcare simulations both indicated that more video-based serious games should be created for nursing education.

Another area where serious games are effective is in building problem-solving skills among students. Games can be adapted to meet a variety of healthcare needs through the patient life cycle from diagnosis to recovery. They can also mostly be played at any time in the day and from anywhere. Serious games are also easy to access, nonthreatening, and fun to play. Text, visuals, and audio cues improve the understanding of the learners without having the restriction of a brick-and-mortar classroom. Scenarios-based learning through games also allows for real-time feedback

that reinforces correct decision-making and procedures followed by the learners. Vital Signs by BreakAway Games – Serious Games Developer Vital Signs: Emergency Department allows learners to practice decision-making in the tension and chaos of an emergency department (Fig. 2).



Nursing Education Through Virtual Reality: Bridging the Gap, Fig. 2 BreakAway games: serious games developer

Nursing Education Through Virtual Reality: Bridging the Gap, Fig. 3 Virtual reality in nursing education: A look at VES available through pocket nurse|HealthySimulation.com

Vital Signs: ED™ – BreakAway Games

Virtual reality-based learning games enable student nurses to assess patients and objectively receive feedback in an immersive environment. Pocket Nurse's Virtual Education Systems VR-simulated learning platform uses avatars to immerse the user into an environment in which he or she would need to interact with a live patient. For instance, a nursing student could practice clinical skills and decision-making on a patient in a hospital setting (Fig. 3).

The student is given an understanding of the reason for clinical decisions and how they are made and also are given real-time feedback throughout the case. This form of experiential learning also drives behavioral change through the repetition of scenarios.

Conclusion and Discussion

Virtual reality as an educational strategy can build on procedural skills, diagnostic abilities, as well as higher-order critical-thinking, clinical decision-making, and communication skills (Lu 2013). Through patient simulations, critical elements of patient safety can be reinforced, such as prevention of errors in medication, practice of good communication, and understanding the importance of collaboration. Learners can be exposed to critical care scenarios and have the opportunity to respond without fear of harming a live patient.

Despite the fact that most studies have proven that VR and serious games help in building engagement and enhancing confidence, and are effective learning tools, there is still a need for addressing human factors such as giddiness through prolonged use (Chang et al. 2020) and ease of use of advanced VR headsets by nursing professionals.

3D object manipulation; Augmented reality; Gesture recognition; User interaction

Definition

Augmented reality (AR) has the ability to blend the virtual and real objects. It enables users to interact with virtual objects or images with a real object as a medium of interaction. Hence, to provide natural and intuitive user interaction in AR environment, real hands are widely explored as an input. This entry explains the natural user interaction using real hand gesture in AR and explains the ARDeco application development process. The fundamental guide to developing AR application for interior design using real hand gestures with Leap Motion controller to interact with the UI and manipulate the objects with hand gestures, including color swatch and texture change panel for UIs and translation and rotation, scaling, create object, delete object, and clone object.

Introduction

Augmented reality (AR) is a technology that allows computer-generated or digital information that includes text, videos, and two-dimensional (2D) or three-dimensional (3D) virtual images to be overlaid onto the real-world environment in real-time setting (Azuma 1997; Mann et al. 2018). AR technology can be a potential solution to create an intuitive way of interaction with the digital content, as it diminishes the boundary between the physical and virtual world by merging them in a same space inside the real-world environment. Even though many research has been carried out in creating various ways in enhancing the experience in using AR,

N. Lee (ed.), *Encyclopedia of Computer Graphics and Games*,
https://doi.org/10.1007/978-3-031-23161-2

interactions that are included in AR interfaces often constrained the users to interact freely and manipulate the AR content as well as prevent them from interacting with it more naturally and intuitively (Billinghurst 2001).

The use of conventional interaction in computers was common and has been used for most people until the current times. However, conventional interaction method that depends on mouse-keyboard-screen interfaces is divided between a space to act and perceive where the input and output devices are separated between virtual and physical spaces (Billinghurst et al. 2015). Hand gestures are one of the possible inputs that can be used in interacting and manipulating the AR content in a natural manner.

User Interaction in Augmented Reality

Researches in human-computer interaction (HCI) explore the ways for intuitive user interaction with an interface. Hand gesture is one of the most influential methods applied in HCI and one of the natural, ubiquitous, and important parts of spoken language (Lin and Schulze 2016). However, for mixed reality (MR), the Hololens device has used user's real hand gestures to catch user's input, while Magic Leap still uses controllers to capture user's input. Hololens and Magic Leap both run independently without the need of computer processing power because it already has its processing power installed within them making them wireless and mobile. Hololens also focused on the development of the virtual user interface (UI). According to Evans et al. (2017), traditional work on AR instructions provided by HMD is limited due to technological defects, but extensive works more into 3D UIs and user interactions can provide insight into potential solutions. However, 3D UIs need a change from 2D WIMP to 3D menus and interactions without a usual mouse. The biggest problem is that all user interactions must be intuitive and accessible through hand gestures rather than a wall, controller, or other physical instruments for optimal functionality. As presented in Table 1, holographic devices such as Microsoft Hololens (2016) and Magic Leap (2018) use a see-through lens in their headsets that enabled the user to see their physical environment while digital information is projected at their respective lenses. Holographic devices still allow the user to see their physical environment where immersive devices, such as

Object Manipulation Using Real Hand Gesture for Augmented Reality Interior Design, Table 1 Devices and experience

Characteristic	Holographic devices	Immersive devices
Example	Microsoft Hololens	Oculus Rift
Device		
Display	See-through display	Opaque display
Movement	Full 6DOF, both rotation and translation	Full 6DOF, both rotation and translation
Example	Magic Leap	HTC Vive
Device		
Display	See-through display	Opaque display
Movement	Full 6DOF, both rotation and translation	Full 6DOF, both rotation and translation

Oculus Rift and HTC Vive, purposely obstruct the user's view from the physical environment with their opaque headset and substitute the user's view with a fabricated digital environment. Table 1 shows the comparison between the holographic and immersive devices.

We examine one of the primary interaction tasks for the AR-based interior design application which is virtual object manipulation. Therefore, there is a need to enhance user's experiences in the augmented world by providing natural user interaction technique for natural and intuitive interaction (Ismail et al. 2015). Hence, there is a need for a better interaction device that uses natural hands and avoids the restriction of hardware between humans and machines to interact with virtual contents (Billinghurst et al. 2015) and promote six degrees of freedom (DOF) to make the experience more engaging in AR-based applications (Ismail and Sunar 2015). In addition, since AR technology is dependent on marker tracking and registration, the problem would be whether the marker is from interacting by hands or other means of physical objects (Azuma 2017); thus, it is important that real hand gesture interaction should be occlusion-free, that is, the hand should not block the marker for seamless tracking (Ismail et al. 2015). This entry aims to describe the implementation of gesture-based object manipulation technique for 3D interior design using real hand gestures in AR.

Virtual Object Manipulation

This section explains the related works and existing projects that have been done by others. Some of the notable works in Tangible AR interface are VOMAR (Kato et al. 2000), Move the Couch Where (Irawati et al. 2006), Studierstube (Szalavári et al. 1998), and FingARTips (Buchmann et al. 2004). As explained in VOMAR (Kato et al. 2000), it has produced a scene assembly prototype of an interior design application for AR. The application consists of a book that holds the virtual models of furniture, a large piece of paper as the workspace, and a marked physical paddle as the interaction metaphor to interact with the models. The virtual object can be manipulated with simple paddle gestures applied to it. Also, an extended and modified version of VOMAR (Irawati et al. 2006) integrates the existing VOMAR prototype. The prototype's functionality is still retained, but it integrates with a speech input system Adriane for specifying commands in object interaction and manipulation. Studierstube project (Szalavári et al. 1998) was a pioneer collaborative AR application that was meant to demonstrate the interface performance using 3D interactive media simultaneously in a collaborative environment. The users wear an HMD, allowing them to view the virtual models in collaboration as it superimposed in real physical world. FingARTips (Buchmann et al. 2004) is an urban planning-based workspace in AR environment that uses a vision-based interaction method in capturing the glove with fiducial markers applied on the wearable glove. The captured part of the hands (thumb and index fingers) can be used to pick up and place the virtual buildings around the workspace. The AR-based mobile manipulation application (Hürst and Van Wezel 2013) was developed to investigate the potential of finger tracking for the use of hand gestures in manipulating objects in handheld devices. This includes evaluation of canonical operations in basic manipulation techniques, such as translating, scaling, and rotating objects.

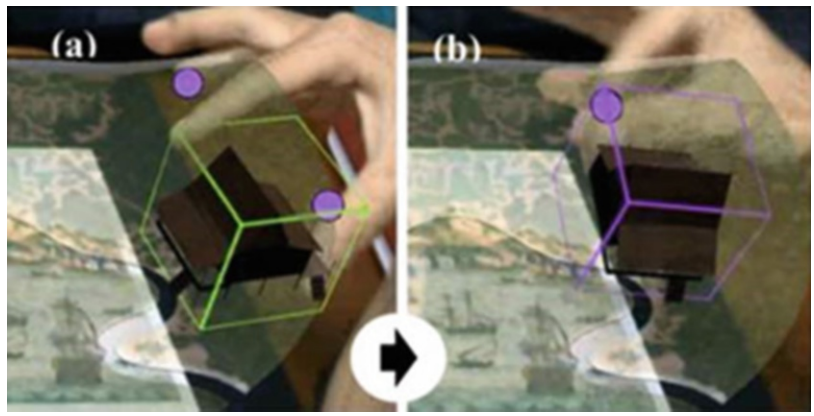
AR-based technology has provided users various interaction means with the virtual objects (Lin and Schulze 2016), and the progressive works in improving the current interaction issues are still ongoing until today (Kato et al. 2000). There is a need to have a better user interaction for AR-based application to make the user experience more intuitive and natural. By integrating virtual object manipulation with real hand gesture in AR environment for 3D interior design application, the user can interact with the virtual object more naturally and intuitively as it diminishes the borders of virtual and real-world environment.

As suggested by (Ismail et al. 2015), for the extended version of Ancient Malacca project (Ismail and Sunar 2015), they have developed an advanced method to improve the user interaction. They have implemented the multimodal

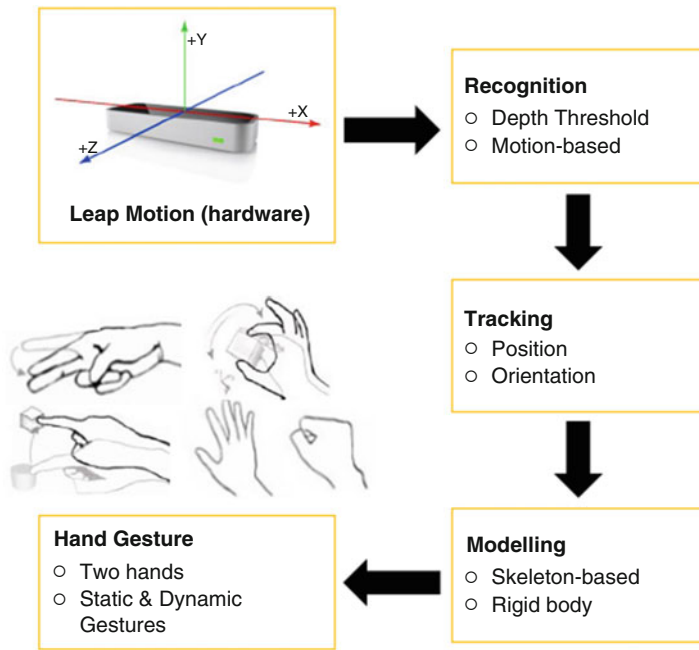
interaction using gesture and speech input, as presented in Fig. 1. The project has implemented the sensor-based hand tracking; the motion data is presented with virtual hand skeleton that is created every time the Leap Motion controller (Ismail and Sunar 2015) senses a real hand in the motion space. The hand skeleton is being drawn in the AR camera view consistent with the position of the image target. The key to high-precision natural hand gesture interaction is high accuracy and high degree of freedom (DOF) hand pose estimation. Their method has proven that it was able to provide 6 DOF natural hand tracking; tracking of the wrist, 15 joints, and five fingertips for both hands at 30 frames per seconds (fps).

Real Hand Gesture Tracking

The following sections describe the gesture recognition process that enables 3D object manipulation for natural gesture interaction using ARDeco (Syafiqa and Ismail 2018) as an example application.



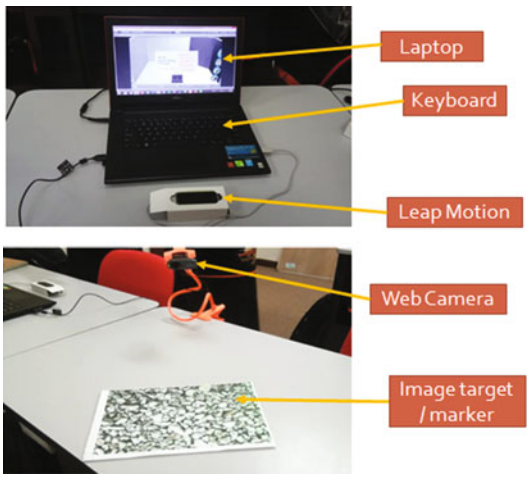
Object Manipulation Using Real Hand Gesture for Augmented Reality Interior Design, Fig. 1 Multimodal interaction technique (Ismail et al. 2015)



Object Manipulation Using Real Hand Gesture for Augmented Reality Interior Design, Fig. 2 Hand gesture tracking method

Stage 1: Gesture Recognition Process

For gesture recognition process, Leap Motion is being used to obtain a depth data. Four stages for the sensor-based recognition process need to be accomplished, as illustrated in Fig. 2. Firstly, the depth data is reproduced by Leap Motion in real time once the device captured the human hands. Next, the tracking process continued to produce pose estimation containing position and orientation. Then, the camera viewpoint pose estimation searches for the hand gesture skeleton to call the gesture shape and 3D representation for both hands. Leap Motion uses raw processing data to perform tracking. The motion data are processed with fingers, and 3D representation of what Leap Motion sees is reconstructed. After tracking the information, the fingers are extracted from the tracking layer. Position and orientation are used to map the 3D representation of the fingers and later used to invoke gestures. Gesture manipulations, including pinch, grab, and release, are implemented in the application. 3D hand skeleton-based interaction using a Leap Motion captures the hand skeleton and identifies 3D finger positions and orientations; thus, we can support a more natural hand gesture-based interaction in an AR scene.

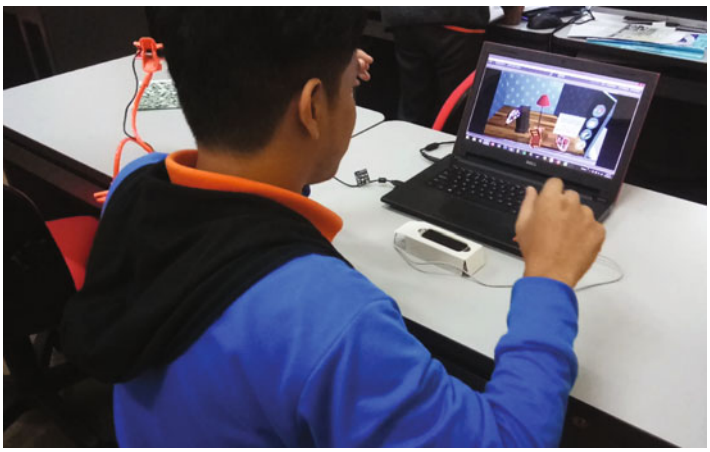


Object Manipulation Using Real Hand Gesture for Augmented Reality Interior Design, Fig. 3 ARDeco application setup

Stage 2: Performing AR Tracking System

The application acts as a platform to integrate the AR tracking with the gesture interaction for 3D object manipulation. For AR to work, the application uses natural feature tracking for more robust tracking. Figure 3 illustrates the AR tracking devices. A personal computer or laptop is used to execute the application; Leap Motion controller is attached to the computer for gesture recognition, while a web camera is used to capture the printed marker. The marker acts as an anchor for the AR environment.

In Fig. 4, AR interface focuses on discovering the manipulation techniques for manipulating virtual objects with hand gesture, including how the user interacts in the AR environment with gestures and basic three-dimensional (3D) spatial manipulation that can be done. ARDeco has come out with a technique for virtual object



Object Manipulation Using Real Hand Gesture for Augmented Reality Interior Design, Fig. 4 ARDeco application with user interaction

manipulation to effectively provide an intuitive and natural way of interaction in AR environment. More about ARDeco will be explained in the next section.

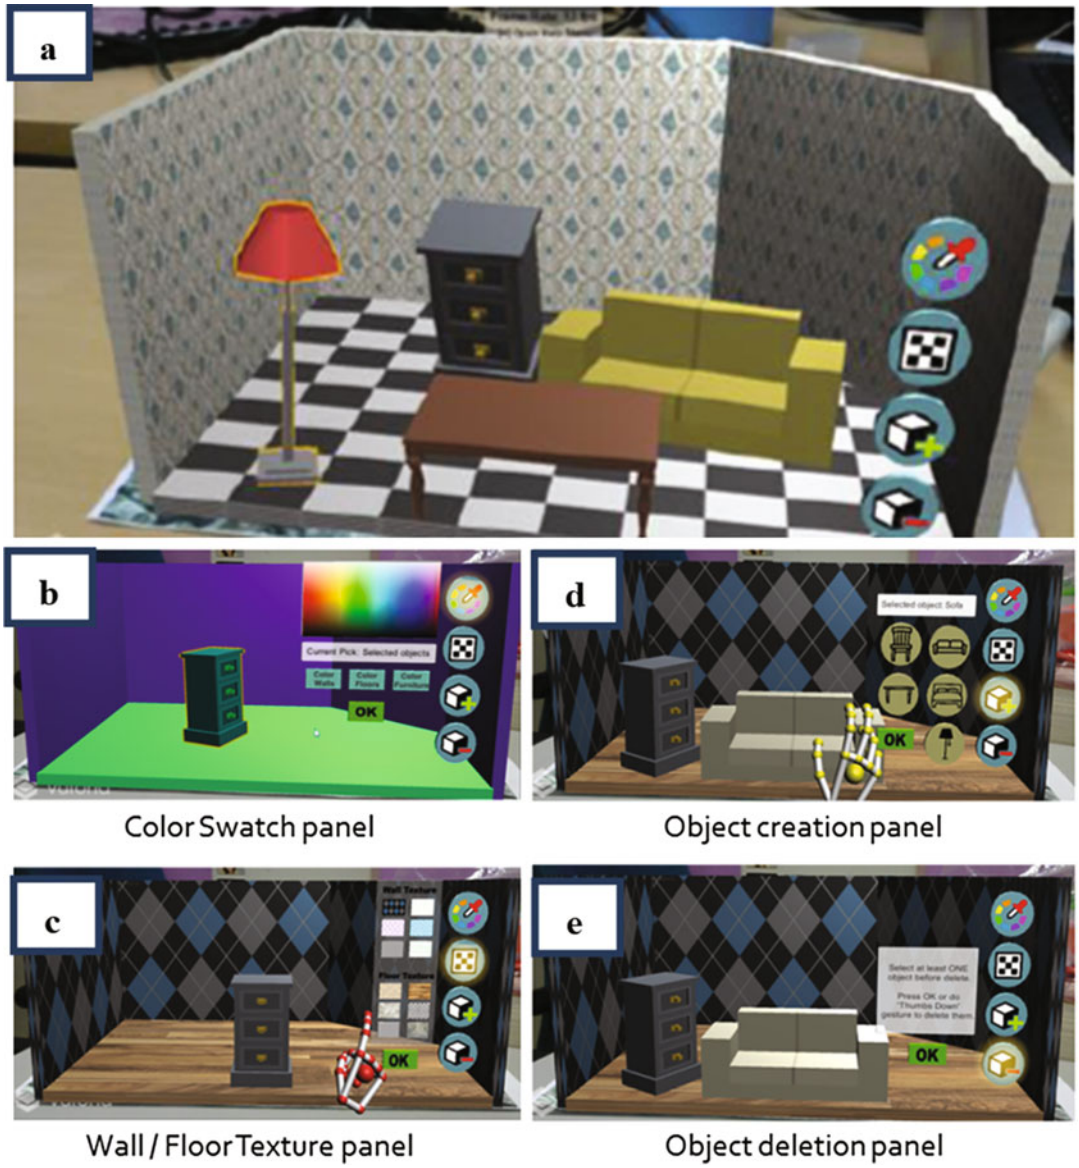
Stage 3: Acquiring 3D Gesture Inputs

The integration of virtual object manipulation using real hand gesture with AR application is described in this stage. The AR application is to use real hand gestures to interact with the virtual elements, including color swatch and a panel to change the virtual object texture. The 3D object manipulation such as translation and rotation, scaling, object creation, object deletion, and object cloning. These manipulation methods are implemented by ARDeco to run a robust virtual object manipulation technique.

Object Manipulation Using Real Hand Gesture for Augmented Reality Interior Design, Table 2 Manipulation task description

Task	Hand gesture	Gesture description
Select and deselect		Extend the index finger and touch the object
Translate the object		Pinch the object with the thumb and index finger to move it around
Rotate the object		Pinch the object with the thumb and index finger and pitch, roll, or yaw the hand to rotate the object
Scale object		Pinch the object with the thumb and index finger on two hands and extend the hands to enlarge or bring them closer to shrink
Create an object		Clap both hands by bringing the palms closer together
Delete object		Extend the thumb finger downward
Clone object		Extend the thumb finger upward
Call menu		Wave the right hand on a certain velocity

The hand gestures for object manipulation tasks such as select or deselect object, move and rotate object, and scaling object are implemented with some modifications. Other manipulation tasks such as create, delete, and clone object do not have specific hand gesture, but the new gesture for these tasks follows the guideline that has been recommended by (Nielsen et al. 2003; Piumsomboon et al. 2014). Common interaction approaches for 3D manipulation are translation, rotation, and scaling. On top of that, users are allowed to pick, drop, change, or remove the selected virtual content from the workspace. The user's real-time finger orientation and movement are obtained via Leap Motion device. Table 2 illustrates the gesture inputs that are used for manipulation task in ARDeco.



Object Manipulation Using Real Hand Gesture for Augmented Reality Interior Design, Fig. 5 ARDeco with real hand gesture interaction

ARDeco: Augmented Reality Interior Design

AR interior design, namely, ARDeco (Syafiqa and Ismail 2018), has a virtual panel that consists of four buttons that can be triggered by gesture in a small range of an AR scene called a virtual room. The room consists of several elements, which are four walls and a floor and a ground. There is also a furniture in the scene that is tagged with certain properties, and this furniture is manipulatable. The color and the texture of this furniture, as well as the walls and the floor, can be changed using gesture input by picking the desired colour inside the color swatch, and the texture can be changed by using the panel assigned to change the object's texture. The color swatch button consists of a color swatch image that can change the object's properties and the color of the furniture object's material. To initiate this function, the user needs to hit the corresponding button using gesture input where it can change the color in real time. After that, the user can use his hand in pointing pose by extending the index finger to select the desired color available on the color swatch panel. The ARDeco application has only five types of furniture, which are a sofa, coffee table, chair, sideboard, and lamp. The furniture would be spawned in the AR scene when a user hits the creation panel. To perform object deletion, the delete button needs to be hitted, and it will only work if an object or furniture is selected. Object selection can be performed by simply touching the desired furniture in the scene.

There are three basic manipulation techniques applied in ARDeco application, which are translation, scaling, and rotation. The user interface of ARDeco lets the user interact with the virtual buttons to perform the manipulation tasks based on gesture inputs. The translation action provides the relocation task, and rotation action gives the furniture's orientation value increase and decrease using the pinch method. The pinch method will be executed when the distance between the index finger and thumb reaches a certain threshold. The rotation action offers the ARDeco the ability to rotate the selected furniture based on the axes in AR interior scene. The scaling provides the furniture with the ability to resize. The task can alternatively be executed with keyboard commands. All of the methods mentioned above will only work if there is or are furniture selected.

Figure 5a shows the overall look of the ARDeco environment with the four buttons that can be seen on the right side of the figure. The virtual room consists of several furniture such as sofa, lamp, coffee table, and cupboard as well as the walls and the floor. The first button, which is the color swatch button, is for changing the selected furniture's color (as in Fig. 5b). The second button is for changing the texture of the selected object, and the user is given 12 types of textures to choose from (as in Fig. 5c). The third button which is the object creation panel is for adding new furniture into the AR scene, and there is a selection of five furniture types to choose from (as in Fig. 5d). The fourth button, which is the object deletion panel, is responsible for removing or deleting the selected furniture from the AR scene (as in Fig. 5e).

Synonyms

Cooking games; Gamification of cooking; Gamified cooking; Multiplayer cooking

Definitions

A cooking game is a game which gives the player/players an opportunity to gain, improve, or demonstrate knowledge or skills related to one or more aspects of cooking.

Introduction

The potential of computer games in teaching cooking remains underexplored despite the amount of consumed food that is not cooked at home, flexibility, control, cost savings and health benefits associated with home-cooked food, and disadvantages of some of the fast food. Limitations of current computer games about cooking include insufficient breadth or depth, resulting in the players getting inadequate knowledge about cooking, and limited ways of challenging the player, rewarding the player, or evaluating the player's performance. This article includes a brief but representative survey of computer games about cooking and introduces many new choices for addressing their limitations.

Cooking Games

Four levels of Overcooked! (https://www.team17.com/games/overcooked) are mentioned by Baek and others (Baek et al. 2022). It is a two-player

cooperative cooking game. One of the four levels requires the players to cooperate. Cooking itself is handled at a highly abstract level in (Baek et al. 2022). No specific recipes or specific missions testing knowledge of cooking, utensils, appliances, or eatable ingredients are mentioned in (Baek et al. 2022). The four levels differ in spatial distribution of tasks and whether the space is shared by the players or not. Bishop and others (Bishop et al. 2020) report on the utility of Overcooked2! in the study of human-agent and human-human teams. Overcooked2! is a game which requires a team of up to four players playing as chefs to complete as many food orders as possible in a short amount of time. Sushi, chicken, pasta, and burrito are mentioned in (Bishop et al. 2020) as the foods to be prepared while playing six levels of this game. The number of steps and ingredients in individual recipes aren't reported in this work.

Bista and Garcia-Ruiz present an overview of cooking games (Bista and Garcia-Ruiz 2021). Some of these are available as apps. Some of the important elements that are relevant to design of Chinese-cooking games are presented in (Cao et al. 2014). These include control over heat (off, extremely slow fire, slow fire, medium fire, and strong fire), ability to select seasoning (edible oil, salt, soy sauce, pepper, sugar, etc.) and other edible ingredients, and the ability to choose cooking action (shaking a spoon, stirring for frying, stirring, and removing and setting aside).

A virtual environment supporting single-player cooking and cooperative cooking for motor rehabilitation is presented in (Gorsic et al. 2018). It is designed to be controlled via wrist and forearm motions. There are three graphically distinct levels of this environment (*salad*, *pizza*, and *buffet*). Salad preparation requires selecting ingredients and dropping them into the bowl. *Buffet* level requires the player/players to locate the correct dishes and place them on the tray. There is an optional challenge that can be switched on and off. To solve this challenge, the player/players have to swat the flies headed toward the salad bowl, pizza, or buffet tray. This virtual environment was evaluated using five unimpaired men and seven unimpaired women. The evaluation involved the following five modes: (i) single player, without flies, (ii) single player with flies, (iii) cooperative playing without flies, (iv) cooperative playing with flies and undefined roles, and (v) cooperative playing with flies and fixed roles.

Dishcover (Mihardja et al. 2019) requires the player to fulfill the set of food orders placed by customers. The player is expected to select an order before its expiration time, but the player cannot select an order without fulfilling the order he/she is currently working on. This requires the player to consider the time needed to fulfill various orders, and prioritize. The actions to perform on an Android phone for frying, selecting ingredients, putting ingredients in the designated area, pouring, waiting, boiling, grilling, rolling, stirring, flattening, grabbing, shaping, and wrapping in the gaming world are described in detail in (Mihardja et al. 2019). The survey conducted to evaluate Dishcover asked the players to rate complexity of gameplay, ease of understanding the interface, immersion, reality, educational value, hours of content, and variety of content (Mihardja et al. 2019).

Express Cooking Train (Mitsis et al. 2019) is a game which expects the player to cook healthy meals that visually resemble junk food and launch them toward monsters to stop them from reaching the train controlled by the player. The player needs to ensure that the train travels farther to earn a higher score. The player is expected to experiment with new ingredients and techniques to enrich the recipes provided, to cook healthier food. Incentives for the player include new recipes, a higher score, and a faster and sturdier train. The player is evaluated based on the nutritional value of the meal prepared by him/her and its similarity with the reference recipe. Ontological modeling is used in calculating similarity with the reference recipe.

The cooking game in (Nakamoto et al. 2008) has an olfactory display. The olfactory display contains solenoid valves, quartz-crystal microbalance sensors, flowmeters with valves, a fluidic low-pass filter, 32 odor components, including the air component, a computer for controlling the solenoid valves, and an air pump. As the player adds ingredients, the player watches a movie on a separate computer and smells the

scent of each ingredient as it blends with those already in the pan (Nakamoto et al. 2008). Foodie (Wei and Cheok 2012) is a system which allows the player to create a food pattern on a mobile phone or tablet PC and craft it at the same or a remote location, e.g., using real sauce to create a message consisting of letters. Foodie is not a game, but it has some game elements. The food-crafting mechanism contains a robotic carriage and the attached food-depositing component with three syringes. The crafting process involves motors' movements and food extrusion. The authors state that the mechanism can only craft using viscous food materials with certain fluidity.

Digital World in Computer Games for Cooking

The world in computer games about cooking can be populated with a refrigerator, eatable ingredients, kitchen utensils, dinnerware, and cooking appliances, including automatic coffee maker, waffle maker, portable electric hot plates, cooking range, sandwich maker, blenders, mixers, microwaves, grills, and toasters. The eatable ingredients can be in different stages, for example, raw, fully cooked, partially cooked, marinated, frozen, sliced, diced, ground, peeled, shelled, or chopped. Diverse digital worlds can be generated by choosing the types of objects in it, the quantities of these objects, the states of these objects, and their spatial distribution. Besides core objects (appliances, utensils, and eatable ingredients), a digital world may have elements for assisting, obstructing, or entertaining the player/players.

Types of Core Challenges in Computer Games About Cooking

In this section, we identify many of the important challenges that can be presented to the players playing computer games about cooking. Many of these challenges are not offered by current computer games about cooking. The challenges are as follows:

(i) Recognizing an eatable ingredient
(ii) Recognizing the function of a kitchen utensil or cooking appliance
(iii) Finding if an eatable ingredient is ready to be used in the given recipe
(iv) Finding operations that need to be used to get the given ingredient ready for use in the preparation of the specified food
(v) Finding the utensils or appliances that need to be used to get the given ingredient ready for use in the preparation of the specified food
(vi) Ordering the given, unordered or incorrectly-ordered steps of a full or partial recipe
(vii) Recognizing the ingredients relevant to the preparation of the specified food
(viii) Recognizing the utensils or appliances relevant to the preparation of the specified food
(ix) Finding whether the given quantities of ingredients are adequate, too less, or too high for preparation of the specified number of servings of the specified food
(x) Estimating the quantities of the given ingredients that are needed for preparing the specified number of servings of the specified food
(xi) Estimating the number of servings of the specified food that can be prepared using the given quantities of eatable ingredients
(xii) Identifying whether the given steps in a recipe can be carried out in parallel or not with the given eatable ingredients, appliances, number of people available to cook, and utensils
(xiii) Reduce the time needed to execute the given recipe, by identifying the steps that can be executed concurrently
(xiv) Estimating the times needed by the given steps, using the given information about initial state of the ingredients, appliances, utensils, the number of servings needed, and the number of people available to cook

(xv) Finding if the given settings of cooking appliances are correct or not for preparing the specified food, for example, temperature of oven
(xvi) Finding the correct settings of the given cooking appliances for preparing the specified food, for example, temperature of oven
(xvii) Finding the most suitable appliance or utensil for the given step in preparation of the specified food
(xviii) Predicting taste of the product of the given cooking steps
(xix) Predicting the effects of the specified change/changes (for example, increase or decrease in the quantity of an ingredient, skipping a step present in a recipe, executing some or all of the steps in a recipe in a different order, change in cooking method, or change in the time for which the ingredients are kept in oven) on the given feature/features (for example, total cooking time, edibility, appearance, weight, color, calories, fat content, carbohydrate content, amount of fiber, amount of protein, texture, or smell)
(xx) Identifying the food or ingredients, appliances, or utensils used in its preparation, based on the given clues
(xxi) Finding the additional resources needed (number of people, appliances, utensils, or quantities of ingredients) to get the given reduction in the total food-preparation time
(xxii) Identifying changes to the given recipe to achieve the specified objective or honor the specified constraints, for example, a reduction in cooking time, energy bill, fat, calories, carbohydrates, or sodium, or creating a gluten-free version of the food
(xxiii) Finding the minimum number of utensils, ingredients, people, or appliances needed to prepare the specified food in the given time
(xxiv) Finding the number of steps in which the specified ingredient, appliance, or utensil is used in preparation of the specified food
(xxv) Completing a partially-specified recipe by choosing ingredients, appliances, utensils, or actions related to cooking
(xxvi) Challenges about activities taking place between the end of cooking and consumption of food, for example, choosing the most suitable containers for serving the foods prepared, serving the foods in correct order, maintaining smell, temperature, and taste, and arranging the food in correct manner on a plate
(xxvii) Finding all or at least the given number of differences between the given foods or recipes
(xxviii) Finding foods whose preparation meets the given cooking criteria
(xxix) Finding the cooking criteria met by the process/processes of preparation of the specified food/foods
(xxx) Finding steps to correct the solvable problems resulting from an incorrectly-executed recipe
(xxxi) Finding the steps which were incorrectly executed, given the problems with the food prepared
(xxxii) Finding incorrect or irrelevant steps, appliances, utensils, or ingredients present in the given recipe
(xxxiii) Finding ingredients, cooking methods, or their combinations that are interchangeable because of acceptable differences in the versions of the food resulting from the substitution
(xxxiv) Finding steps to modify a correctly-cooked food to meet the specified criteria
(xxxv) Finding a new recipe consistent with the given template
(xxxvi) Ordering the given ingredients, utensils, or appliances based on the number of recipes from the given set of recipes in which they are needed
(xxxvii) Finding the most similar or most dissimilar recipes or foods from the given set

(xxxviii) Clustering the given foods based on the given criterion, for example, putting appetizers, desserts, and entrees in three separate clusters, or putting the foods that can be prepared in 30 or less minutes in one cluster, putting the foods taking longer than 30 min and less than 60 minutes to prepare in second cluster, and putting the foods taking 60 minutes or longer to prepare in the third cluster

(xxxix) Ordering the given foods or recipes according to the given criterion, for example, number of ingredients, cooking time, energy consumption, or number of appliances needed

(xl) Matching the given ingredients, appliances, actions, or utensils with the given foods based on their relevance in the preparation of these foods

(xli) Finding whether the given ingredients, appliances, or utensils are essential in the preparation of the specified food or not

(xlii) Identifying the steps needed in special situations, for example, cooking outdoors when it is windy, extremely hot, or when there are flies

(xliii) Choosing the correct ingredients to use in cooking each day when there are enough ingredients for preparing foods for multiple days, considering the expiration dates, best-by dates, or appearance of ingredients to minimize wastage

(xliv) Combinations of previously-mentioned challenges, for example, cooking a dish from scratch, or cooking multiple dishes

Entertaining, Rewarding, and Motivating the Players

The games can be made entertaining by including animations, sounds, pictures, jokes, stories, and non-playing characters. These can also have the effect of motivating or rewarding the players.

The players can be motivated in many ways, for example, providing bonus ingredients, facts about food, facts about parties, cooking tips from top chefs, information about how much they can save by cooking instead of eating at a restaurant or getting the food delivered or picking it up, inclusion of the player's/players' recipe in the next version of the game or a digital book of recipes, or providing incentives in the real world, including execution of their recipe in the real world by a third party and delivery of real food to people of their choice, invitation to cook at a real restaurant, inclusion of the player's/players' novel recipe in the menu of a restaurant for a certain period, inclusion of the player's/players' novel recipe in a physical recipe book, invitation to a cooking show on television either as a contestant or as a judge or as a host, a share of the revenue obtained from commercialization of the player's/players' recipe/recipes, discounts at grocery stores, restaurants, or discount on health-insurance premium, fees of cooking classes, or membership fee of a gymnasium. These can also be seen as ways to reward the players.

The rewards can be in the form of additional ingredients, additional quantities of ingredients, additional or more efficient utensils or appliances, extra time for cooking, additional people to help in cooking, automatic execution of some steps to help the player, or hints for reducing the difficulty of challenges. These can also have the effect of motivating the players. There are other ways to reward the players, e.g., by providing a bigger or renovated kitchen.

Designing the Levels of Computer Games About Cooking

Different levels can differ based on the types of challenges and/or numbers of challenges. Levels can also be designed based on how people typically learn to cook and apply what they learn. We provide a list of levels next, but other alternatives exist.

Level 1: Testing knowledge of eatable ingredients, appliances, and utensils

Level 2: Choosing suitable ingredients in suitable quantities, and performing suitable operations using suitable utensils or appliances in suitable order to create one food for consumption by one person

Level 3: An augmentation of the challenges in Level 2 because of the player being required to create a multi-course meal

Level 4: An augmentation of Level 2 because of the player being required to cook the food for consumption by multiple people, and hence being required to perform calculations about quantities and servings

Level 5: An augmentation of Level 4 because of the player being required to cook a multi-course meal

Level 6: An augmentation of Level 5 because of the player being required to cook multi-course, multi-cuisine meals

Levels can also be created based on the courses of a multi-course meal. The first level can be for soups, the second level can be for appetizers, the third level can be for salads, the fourth level can be for the main course, and the fifth level can be for desserts. Levels can also be created based on the total food-preparation time. The first level can be for foods taking 15 or fewer minutes to prepare, the second level can be for foods that take more than 15 min but not more than 30 min to prepare, the third level can be for foods that take more than 30 min but not more than 1 h to prepare, and the fourth level can be for foods than take longer than 1 h to prepare. The levels may be based on the types of places serving food. These include food carts, food trucks, food halls, fast-food restaurants, casual-dining restaurants, and fine-dining restaurants. Levels can also be based on occasion. The first level can be about cooking on weekdays. The second level can be about cooking special food on weekends. The third level can be about cooking for family events, including birthday celebrations. The fourth level can be about cooking on public holidays with special foods associated with them, e.g., turkey and Thanksgiving. There can be more than five levels. Additional levels can be created by including additional constraints, by including temporal deadlines, dietary restrictions, limiting the quantities of the ingredients shared by multiple recipes, limiting the number of times a specific utensil or appliance can be used, or constraining the temporal intervals during which the player can access certain ingredients, appliances, utensils, or areas of the cooking world due to others needing these resources for their cooking. There are other ways to make higher levels more complex. Having many challenges in one level may discourage the player because of long time or multiple gaming sessions needed to get to the next level.

Evaluating the Player

In general, a player can get or lose points based on the correctness of choices related to ingredients, appliances, utensils, quantities of ingredients, cooking methods, wastage of ingredients, order of the steps executed during food preparation, total duration of food preparation, or durations of individual steps, and satisfaction of additional requirements, including dietary constraints. The specific scoring method will depend on the challenges presented to the player.

Multiplayer Versions of Computer Games About Cooking

Different players can cooperate or compete. If there are multiple players but no teams, then the players can be ranked based on scores. If multiple players have an equal score, then additional criteria can be used to rank them, for example, the total number of attempts needed before correct choices were made. When teams of players can be formed, a player can have a specific set of roles. For example, one player can be in charge of getting the ingredients ready for cooking, another player can be in charge of mixing the relevant ingredients and carrying out the correct operations in correct order using correct utensils or appliances, and the third player can be in charge of monitoring the entire process and correcting mistakes in a timely manner, when there are three players on a team. The actual distribution of responsibilities among the players depends on the

challenges, their skills, and the levels of these skills. When players compete, core challenges can include getting the right ingredients in right quantity or state, getting access to utensils or appliances, protecting the ingredients or their combinations at various stages to preserve edibility, shape, arrangement, smell, taste, or temperature, and even getting space to work on individual ingredients or their combinations at various stages. Players can lose points for being obstructive or destructive, intentionally or unintentionally, and negatively affecting competing or collaborating players as a result.

Online Gaming Architectures

Stefano Ferretti and Gabriele D'Angelo
Department of Computer Science and Engineering, University of Bologna, Bologna, Italy

Synonyms

Distributed architectures for online multiplayer games; Gaming infrastructures; Multiplayer online gaming architecture; Networked gaming architectures

Definitions

Online gaming architecture refers to the distributed system architecture that is employed to support an online game session with multiple participants, geographically distributed and connected through the Internet.

Networked Multiplayer Games

Networked multiplayer games are contributing to an increasingly large proportion of network traffic (Suznjevic et al. 2013). In order to support massive multiplayer online games, users must be provided with scalable architectures, able to handle a large number of players geographically distributed over the network that play together. This

forces the use of specific solutions, specifically thought for online gaming applications.

Problems of Networked Multiplayer Games

An interesting approach to evaluate the effectiveness of a gaming architecture consists in considering the well-known "Eight Fallacies of Distributed Computing" (Wikipedia 2017). According to Peter Deutsch: "Essentially everyone, when they first build a distributed application, makes the following eight assumptions. All prove to be false in the long run and all cause big trouble and painful learning experiences." In essence, these eight fallacies and assumptions contribute to poor user experiences and must be accounted as fundamental principles during the design of a scalable architecture.

The eight fallacies are:

1. *The network is reliable*. The larger is the number of entities composing the distributed architecture, the more this assumption results false. Thus, sophisticated mechanisms that provide reliability without affecting the interactivity and responsiveness of the game system must be devised.
2. *Latency is zero*. Latency is a main issue in online games. Indeed, high delays and high delay jitters may impair the responsiveness of the system and render the gaming activity a frustrating experience to users.
3. *Bandwidth is infinite*. In wide area networks (and Internet), this assumption is definitively false, due to network congestions and bandwidth bottlenecks.
4. *The network is secure*. This fallacy is common to most distributed systems; in games, cheating-avoidance approaches (Ferretti 2008) and intrusion-prevention mechanisms must be adopted.
5. *Topology doesn't change*. In the Internet, link failures and congestions may result in topology changes that may alter (improve or degrade) transmission delay and jitter. In this sense, cloud computing services now provide new mechanisms to surmount these problems in networked games.
6. *There is one administrator*. Even if in current (centralized) gaming applications this statement can be considered as valid, supporting a large-scale networked game might require a decentralized control of some shared resources.
7. *Transport cost is zero*. In the Internet, users (providers) have costs in order to access (provide) the service.
8. *The network is homogeneous*: This assumption is obviously false. Moreover, the heterogeneity of the network is going to increase now that new mobile technologies offer diverse typologies of network services to customers.

Online Gaming Architectures

In order to support game applications with players geographically distributed and connected to the Internet, several architectural solutions have been presented in the research literature and in commercial products. It is possible to distinguish among the following:

- Client-server architectures
- Peer-to-peer architectures
- Distributed architectures

In essence, an online game architecture is typically composed of two types of entities: client entities (CE) and one or more game state server entities (GSSE). A CE is a client software application that performs input/output with its player and receives/notifies events from/to the GSSE to which it is connected. Stated simply, a CE acts as a viewport to the game state and passes commands issued by its players to the GSSE. Using the terminology derived from the IEEE 1516 "HLA standard" for distributed simulation (IEEE 1516 Standard 2000), a CE may be seen as the owner of one or more virtual entities and is responsible for updating the state (e.g., value) of their attributes (e.g., their position). Moreover,

a CE is also in charge of performing graphic renderings. Instead, a GSSE maintains the game state, or a part of it (Marzolla et al. 2012).

In a client-server architecture, there is a single GSSE, while all gamers execute a CE in their exploited device. In peer-to-peer architectures, each node executes both GSSE and CE functionalities, thus requiring a synchronization mechanism among all GSSEs in order to keep the game state at each GSSE synchronized with others. Distributed architectures are a sort of in-between solution, exploiting a subset of nodes in the architecture acting as GSSE, while the majority of gamers' nodes execute only CE functionalities. This solution aims at distributing (and/or replicating) the task of game state management, while at the same time keeping limited the amount of nodes involved in this task, and thus limiting the workload for the synchronization among these nodes.

In addition to the two mentioned game software entities, to enhance players' experiences, also other ancillary services could be provided in the game environment (Wright and Tischer 2004). While some of these services strictly relate to the game (such as the already mentioned game state management provided by GSSEs), others may have only tangential interest to the game play mechanisms (Okanda and Blair 2004). Summing up, a game architecture should provide support for:

- State Maintenance: GSSEs maintain the game state that is composed of the virtual world representation and of the state of all the involved characters.
- Consistency Maintenance: Due to latency, timing relationships may be distorted in the simulated world causing anomalies and inconsistencies. Thus, functionalities are needed so that players perceive the same evolution of the game.
- Group Management: Not all the players are interested to receive exactly the same messages. Thus, grouping of players and event filtering schemes may be utilized. Grouping and event filtering typically relate to some semantics of the application (e.g., players in the same room receive same events), but they could depend also on the client configurations (e.g., clients with low bandwidth connections or with a low computation capacity may receive less detailed information than clients with high speed connections and a high computational capacity).
- Event Delivery: Each generated event has to be sent to other players, so that each participant to a gaming session perceives the same updates during the game evolution.
- Accounting, Authorization: Before starting the game, an initialization phase is possible where each client configures and negotiates parameters with the GSSE to better enjoy the service. Moreover, these services validate players to play a particular game.
- Cheating Control: Each event generated by a player on the virtual world has to be checked so as to prevent cheating (Ferretti 2008).
- Player Communication: Traditional interpersonal communication mechanisms may enhance the game activity, enabling players to chat, send instant messages, or even interact in audio/video conversations (Wright and Tischer 2004). Nowadays, playing games while interacting with other players is quite popular. In this sense, the current approach of online gamers is to resort to external VoIP-based tools to communicate with their gaming friends. This is probably due to a lack of viable solutions offered by online gaming architectures. Actually, there are plenty of such tools, and while any kind of VoIP tool might work, services exist that are made especially for gamers. Examples of these services are Discord (https://discordapp.com/), TeamSpeak (http://www.teamspeak.com), and Ventrilo (http://www.ventrilo.com/). They enable players installing specific applications on their devices as well as using novel Web-based technologies, e.g., WebRTC.
- Multimedia Resource Distribution: When describing a game architecture, the common approach (in literature) is that of considering the resource download activity as an "offline"

task accomplished before starting the game (Bangun and Beadle 1997). Instead, we believe that multimedia distribution activities will massively come into the future game picture. In fact, the new games that are being developed are very dynamic, with players (and most of all, mobile players) that dynamically retrieve all the needed resources to interact with other players.

Online Gaming Industry Evolution, Monetization, and Prospects

Swapnil Pande
Product Designer (UI/UX), Delhi, India

Synonyms

Electronic sports; Playing; Recreation; Sporting life; Video games; Web gaming

Definition

Online gaming is basically the playing of a computer game over the web, generally with companions. Web-based games can be played on quite a few gadgets from devoted gaming consoles like PlayStations, Xboxes, and Nintendo Switches, to computers, PCs, and cell phones.

Introduction

The gaming industry is one of the biggest and fastest-growing industries. Millions of people around the world are unboxing and downloading videogames each day making this industry even bigger than the movie and music industry combined (Fig 2). It's pretty incredible how much the gaming industry has evolved throughout the years. From MIT scientists making a first video game in their basement in the 1970s to the race of developing home gaming consoles and computer games in the 1980s and 1990s to the whole new market of online gaming in the 2000s and now mobile gaming and eSports (eSports is a form of sport competition using video games. eSports often takes the form of organized, multiplayer video game competitions, particularly between professional players, individually or as teams.) where fulltime professional gamers attract stadium full of crowd and earn millions of rupees.

According to Al (2019):

- In 2016, a third of the world's population was video gaming which is 2.5 billion people.
- In 2017, about 660 million people were interested in watching people play video games on platforms like Twitch and YouTube.
- In 2018, the whole gaming industry made at least 130 billion dollars.
- The gaming industry is rapidly growing by about 10% per year.

Gaming can no longer be considered as just a hobby and to portray it as a niche market is an understatement. It's a blasting industry with wide space for development. Furthermore, with constant advancement and the starting of more game contributions, we can just imagine a splendid future for the gaming business. The fast ascent of innovation will carry the business to different domains, for example, cloud gaming, VR (computer-generated reality) gaming, and AR gaming.

In an interview with legendary game designer John Newcomer (Newcomer 2015):

> Games have to continue to evolve over their lifetime with a series of updates. In general, the games keep giving the player more things to do. New play modes get added, daily quests. More games have been adding a PvP (player versus player) component.
>
> The game starts out as a single player experience and then it evolves into competing against other players. Then you see more community features added like chat, special events. The whole game feels like a party.

Global Active Gamers

Xbox

Microsoft revealed some important new Xbox stats (Warren 2020):

- Xbox Live has nearly **90 million** monthly active users.
- Xbox Game Pass has more than **ten million** subscribers.
- Project xCloud has 100 s of thousands of active users in preview.

PlayStation Network

First launched in November 2006, PlayStation Network (PSN) is a digital entertainment service associated with Sony's PlayStation series of consoles. It has since been expanded to run on smartphones, tablets, and HD televisions.

As of August 2020 (Gough 2020)

- The network had approximately **113 million** monthly active users.
- A significant increase from the **50 million** users in March 2014.

Evolution of Multiplayer Gaming

Multiplayer is one word for many different meanings. To some it's a way of life, even a path to fame and riches and to others it's a chance to have fun with their close ones.

The history of multi-players is as old as the history of gaming itself. Even as far back as the 1950s, the supposedly game of tennis was meant to be a two-player game.

After a long leap there came a game called "Maze War" in 1971 developed by NASA. Maze was the first real FPS (First-person shooter) game in which two computer screens are connected directly to each other and let two players hunt each other down in a twisty deathmatch. In these early days, this experience was achieved by hooking up serial cables between two machines as the internet was not yet developed.

Internet was introduced in 1991, and as soon as in 1993 DOOM was introduced and its network FPS coding changed the industry. Now players can connect up to four computers using LAN (local area network) to play for fun or competitively. A year later in 1994, an early online gaming matchmaking service was introduced which allowed players to connect over the internet and the blueprint for every multiplayer shooter thereafter was drawn.

DOOM's phenomenal success and excitement in the masses didn't go unnoticed. In 1996, QUAKE released, and the big thing about quake was its multiplayer run from servers. Everyone

connected to one server could find each other and now the player didn't have to enter the IP address (Internet Protocol) to find other players. This was multiplayer made easy. It was such a big hit and a landmark in the history that new-age popular games like CS (Counter-Strike) and OVERWATCH took inspiration from its design and strategy.

In the year 1997 Quake also provided a venue for the first-ever eSports tournament and it was called RED ANNIHILATION and the winner got to drive off in John Carmack's Ferrari 328.

All through the 1990s, first-person shooters ruled the sales, mainstream awareness, and the multiplayer; but as the internet became more household-friendly across the globe, opportunities for developers also broadened and so came MMORPG (Massively multiplayer online game).

Games like "Meridian 59" and "Ultima online" popularized the genre of the fantasy land where gamers could create alter egos and live out second lives as Knights, Farmers, or the ruler of the kingdom. The world populated by real players spread like wildfire but the games like "World Of Warcraft" that came out in 2004 gave the genre place of mainstream title.

On the other hand, as the computers become a household necessity, it gave strategy games great opportunity to flourish. Games like STARCRAFT, which is now a big name in the eSport world and hosts million-dollar prize pool tournaments, were introduced in 1998. It sold 9.5 million copies in the next decade and made its place in South Korea. South Korean TV broadcasted eSports tournaments and that gave the competitive gaming an identity.

In March 1999, "Counter-Strike" was released and by the end of the year, it was one of the biggest things in the gaming industry. CS and Quake 3 both made a pretty big impact as with the internet connection at home now anyone can do multiplayer gaming.

In 2002, DOTA emerged from the mods (A mod is an alteration by players or fans of a video game that changes one or more aspects of a video game, such as how it looks or behaves.) of the old starcraft map and people loved it. In the present date, DOTA is one of the biggest games and a big part of eSports tournaments.

In the year 2016, gamers enjoyed an "ARMA 3" mod so much that by the year 2017 it became PUBG (Player Unknown's battleground), the biggest game in the world. It attracts double the play account of DOTA 2 every day. Usually have over a million players online at any given moment and has sold over 20 million copies so far.

Games and gaming experience have come a long way but this was not possible without the technology involved in gaming. From PCs and consoles to Smartphones are the only reasons we can perform such high-level gaming.

In an interview, John Riccitiello, CEO of Unity Technologies, said:

> The scaling of the industry is driven by technology, so if you go back a decade or two ago, back to 1997 all games were 2D because you couldn't power a 3D game through the CPUs and GPUs weren't . . . It wasn't possible. You Couldn't do online gaming, you couldn't connect to another live player and for the most part, you were strapped to the device parked under your TV or your large desktop PC and that's all is not true any longer. The available computers are up to many millions of fold to the consumer on a global scale, networks work better than ever before and that was 2D became 3D, non-interactive became interactive, and non-social became social and in that there are more players than TV watchers or music listeners on basic and the consequence of that taking advantage of the technology that fueled its growth. Cause when I entered the industry it was much smaller than the music or TV industry but it is much larger than the two of them combined. (Riccitiello 2020)

Evolution of Video Game Console

- In the year 1972, first ever console was launched known as Magnavox Odyssey.
- After seeing the interest in the market about gaming consoles several companies launched several consoles to compete with each other. In the next 18 years, almost 15 different models were launched by all around the globe.
- In the 1990s the competition was at its peak and every major company was trying to break-in.

- In the next 10 years, around 17 different consoles were launched including PlayStation in 1994 and Nintendo 64 in 1996.
- After 6 years, in 2000 PS2 was launched and by this time the console industry was slowing down its speed.
- In 2001, Xbox was launched.
- From 2001 to 2020, only 10 consoles were launched and just a few companies were left in the market to compete. Just four companies, namely PlayStation, Wii, Nintendo, and Xbox, launched their consoles in the last 20 years.

Evolution of Mobile Gaming

Mobiles are smartphones now and they have come a long way from being a small telephone to a superfast and capable computer on your palm. The things one can do with smartphones nowadays are limitless. Mobile games were always welcome, and as the hardware grew more powerful, the developers started taking more interest in the opportunities.

- In the year 1994, Tetris was launched in the Hagenuk MT-200 with a black and white display.
- In 1997, "Snake" was launched in Nokia 2170, and it's still a very integral part of every 90s kid.
- Nokia came out with Snake 2 and Alien Fish Exchange in the year 1999 and 2000, respectively.
- In the year 2001, Sonic the Hedgehog became the first colored mobile game.
- In the next decade, several 2D games were launched ranging from racing to strategy.
- In 2011, Grand Theft Auto 3 came out and it became the first 3D game for the mobile gaming industry.
- In 2011, Mini Militia, and it was the first multiplayer game in which players could connect through LAN and play together. It was a big hit among college students.
- In 2012, Supercell launched Clash of Clans and it became one of the biggest games. COC was the first online multiplayer strategy game for mobile phones.
- In 2013, Asphalt 8 racing game was launched and cruelly challenged graphics provided in mobile phone games.
- After a year of launch, in 2018 PUBG Mobile was launched and it became one of the biggest games to date. PUBG Mobile also organizes several multi-million prize pool tournaments all across the globe and has changed the eSport structure of mobile gaming.
- In 2019, Call of Duty: Mobile was launched with the same idea as of PUBG but was a slow burner.

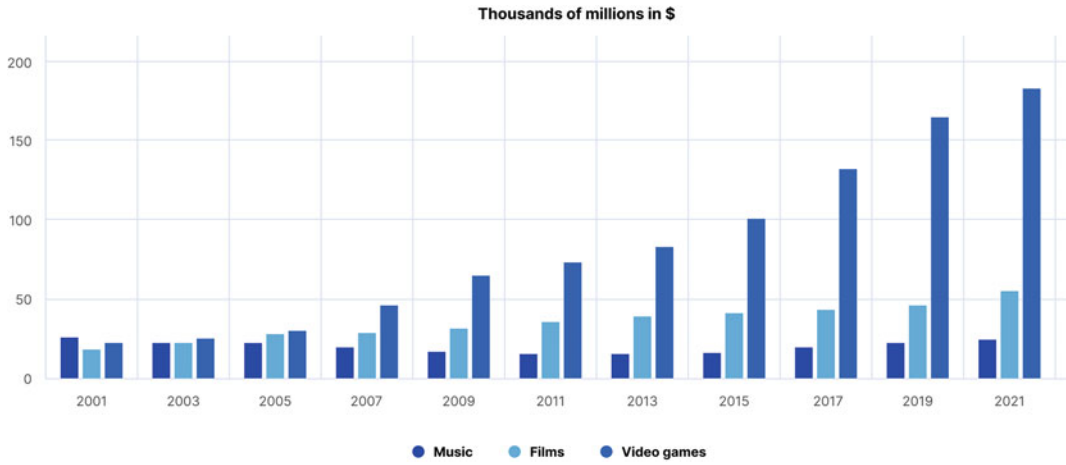
The New Era of Monetization

Today there are 2.4 billion gamers all around the world, and the technologies like blockchain technology (Blockchain is just a record of digital transactions. Blockchain records any transactions made with cryptocurrencies such as bitcoin and Libra) will unlock new opportunities for them to become creators, entrepreneurs, and service providers.

As more and more people around the world are playing in PCs, consoles, and smartphones, more people are looking to break into the industry and make a living doing it. With time gaming companies are also adopting different ways to earn money.

At the turn of the century the gaming market, the global box office, and the music industry were about the same size but over the last 19 years the gaming market has seen immense growth, and as of 2019 the gaming industry is a $150 billion market, it's larger than the music and film industry combined together, and it's been that way for last 8 years and the gap is only growing (Fig. 1).

PC game industry as of now gets more cash-flow versus movies and music industry combined. It's not because more individuals are messing around when contrasted with watching films but because of the imaginative income models that the gaming business has presented over the previous decade.



Online Gaming Industry Evolution, Monetization, and Prospects, Fig. 1 Thousands of millions in $
Source: (Zeeshan 2020)

In-application purchase, in-game promotions, development packs, season pass, restricted version skins/ensembles, and so forth to give some examples. Although film industry income streams separated from the development of OTT stages have essentially been the equivalent.

Fortnite is one of the biggest battle royale games with millions of viewers each day and it's free. This is because of the new model gaming companies have adopted and that is micro-transactions, that are selling things in the game itself. For example, if the person wants to upgrade the look of the avatar or wants to buy skins for the guns or wants to buy an extra life, it is just a small transaction away. Fortnite made about $2 billion dollars in 2018 despite being a free to download game.

So the idea is despite paying for everything upfront, the gamer is now paying in little streams of $1, $5, and $10 to the game company and it turns out the company makes tons more money in that model than they ever did back in the day. This money pouring into a lot of games isn't coming from casual gamers, it is coming from a small group of big spenders known in the industry by a very special name: "Whales."

> A whale is a player that spends a lot and plays a lot. They love this game and they love being powerful and special and the big spenders will drop $2000 to $3000 a month. (Perianez 2018)

Whales make up just a tiny fraction of total players but then can generate more than half of the games' total revenue. This means finding and nurturing a potential whale is the real game.

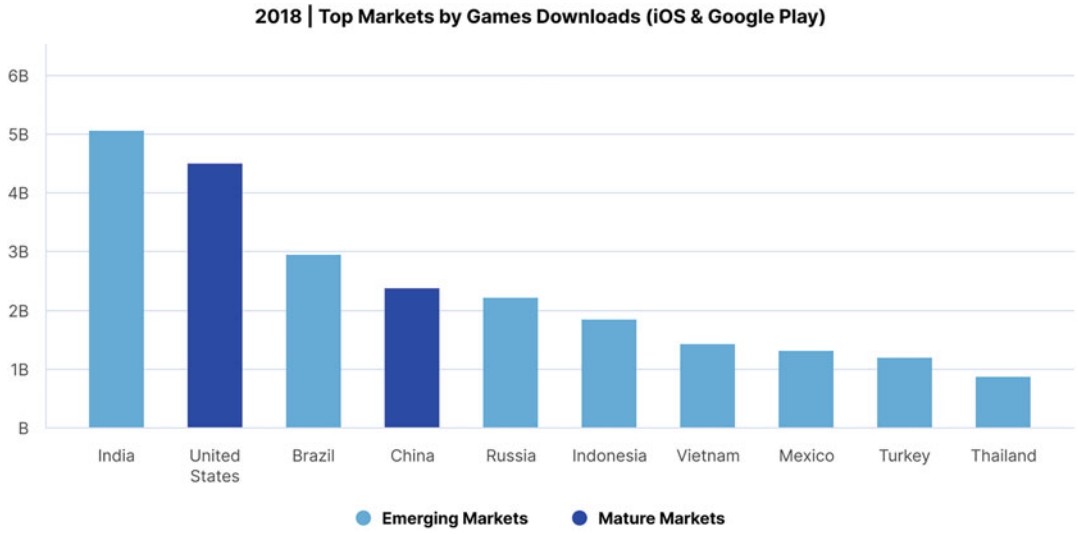
Several big-time business tycoons are now purchasing professional gaming teams and this not only helps in generating revenue from the tournaments and brand deals but also from viewers who are willing to watch the stream and influence other casual gamers to potentially convert into whales.

Computer games as a Sport are additionally a developing pattern wherein future projections show that eSports will be as large as NBA, EPL if not greater. Starting today, eSport competitions are the biggest gaming tournaments that occur.

Games are not only a multi-billion-dollar business but at the same time, it is making a huge cultural difference too. Several movies are being made based on videogames like Prince of Persia, Tomb Raider, and Assassin's Creed. Each movie has done great box office collection and has attracted A-Listed talent like Angelina Jolie, Jake Gyllenhaal, etc. Also several talented and famous actors are more than happy to play a role in the game itself too.

Making Living Out of Gaming

The concept and idea of monetization has completely changed over the years. Traditionally



Online Gaming Industry Evolution, Monetization, and Prospects, Fig. 2 2018 | Top Markets by Games Downloads (iOS & Google Play) **Source:** (Zeeshan 2020)

making a living in the gaming industry was about making games itself. Early on games were often made by a single person and all the money made from the game was up for grab but now the scale is a lot bigger. A large number of development teams to marketing teams give their blood and sweat to develop a game. But now not only developers but gamers are also earning big numbers and people don't even realize or consider it as a career option.

eSport is one of the biggest growing but underrated career options. Kyle Giersdorf, a high school junior at the age of 16 years, qualified for the Fortnite World Cup Finals from a field of 40 million and went on to beat 99 players at Queens' Arthur Ashe Stadium to become the eSports' first solo champion, taking home $3 million in prize money in a 3-day tournament. This is much more than the prize money of any major sports tournament.

And not just this, there are salary opportunities in this too. The average salary for a League of Legends player is about $320k a year and this is only possible because of the enormous viewership. About 99 million people turned-in to watch the championship event, and it was broadcasted in 19 different languages across 30 different platforms including ESPN.

The tickets to these kinds of events sold out within a day and this can very much explain the enthusiasm and motivation of people toward this industry.

Apart from professional tournaments, streaming also contributes to gamer's popularity and revenue. Streaming is where a gamer is playing a videogame and broadcasting it over the internet for anybody to watch via platforms like Twitch and YouTube. Streaming gives the viewer the power to enjoy the game without having the skill part to complete the game. Not just professional gamers but casual gamers are also streaming games, and according to the numbers, people are enjoying it.

Ninja is one of the most famous streamers in the world and through his fan subscriptions also he makes $500k a month, and this is without even including his endorsements deal like his Adidas partnership or such as his appearance fees like hosting Red Bull's new year party at Times Square.

So taking this as an example it is very clear that the monetization method has increased the opportunities all around us.

Today people earn a living in gaming in three ways:

O

1. Develop Game
2. Professional eSports
3. Game Streamer

Even with these new opportunities, the chance to make it into the industry is still incredibly tough. For example League of Legends, there are over 100 million active players in this game today whereas today in the entire world there are just under 1000 professional players and that's 0.001% of the people that can make it to the pro leagues.

On Twitch (Streaming Platform), there are over three million active streamers a month, but of that only 10 thousand are in Twitch's partner program making a full-time income that is 0.33%. So, to think it through before joining and career path is very important.

Conclusion

We can say that gaming is not simple entertainment now. It has become a grand business model with enormous money and status involved. World level industrial houses are entering in gaming industry and applying all possible strategies to face cut-throat competition.

Online Gaming Scalability

Stefano Ferretti and Gabriele D'Angelo
Department of Computer Science and Engineering, University of Bologna, Bologna, Italy

Synonyms

Game performance

Definitions

Online gaming scalability refers to all those techniques that aim at supporting online game sessions with a variable amount of participants. No matter the amount of players, the online game session must provide a fluid, compelling, and responsive game evolution.

Scalability Issues

Today, almost all games have some online components that enable users interacting in an online game session. The high demand for such online services poses several scalability issues. The service must provide enough capacity to handle all requests and scale with the number of players they need to serve. In general, scalability indicates the capability of a system to maintain its performance under an increased load (Jogalekar and Woodside 2000). The demand for scalability is an issue common to all distributed systems and applications. Online games do have such need as well, which is complicated by the fact that at the same time, a high level of responsiveness must be

maintained, in order to provide a compelling gaming experience to all the players.

There are different possible approaches to manage a high amount of players: a solution is to increase the resources devoted to handle the application; then, it is possible to reduce the amount of interacting entities; finally, it is possible to reduce the communication required to handle the game state evolution.

Increasing the Resources

The idea of this approach is quite intuitive: the more players are playing the game simultaneously, the more resources are needed to handle the game state and the interactions among players. This approach is the common one used in every type of online client-/server-based application, i.e., as soon as the amount of clients increases, the service provider needs a more powerful server.

The server must be able to manage the user requests during the peaks. Overprovisioning the server might be a solution. However, when there is a lower amount of players wanting to play, this solution wastes capacity. For instance, this might happen at night, when most players are not playing; thus big parts of the server are idle.

The advent of cloud computing solves this issue. This architectural approach provides the combined computation and storage resources of an undetermined number of machines to other devices at arbitrary locations on demand. Resources can be added or removed on demand, based on the amount of users. This is the most used architectural approach to support current online games (Marzolla et al. 2012).

Partitioning Techniques

Partitioning techniques are an alternative approach that is typically combined with the use of multiple server resources, so as to increase scalability. The idea is that if there are too many players willing to play a game, it is possible to instantiate multiple servers and distribute the player across these multiple instances.

In some cases, the servers are mirrored, and they manage the same game state evolution. This architectural solution benefits from the partitioning of the players across multiple servers; however, servers must synchronize their game state updates in order to guarantee a consistent and correct evolution of the game state (Palazzi et al. 2006).

In other cases, the server instances are set independent from each other. Each server has its own game session which has nothing to do with others running on other servers. As an example, imagine a large virtual world that is partitioned into different regions, and each server is responsible for a given region. Another example is that each server is responsible to manage a different game session, involving a specific subset of players. For instance, think at a sport game session with a limited amount of involved players. In order to make sure that players are distributed evenly across all servers, different load balancing strategies can be used.

Communication Reduction Mechanisms

The many entities (e.g., avatars, non-player-characters, environment) participating in an online game need to interact for exchanging data. For example, the position of each avatar in the virtual world must be timely updated. This data is often encapsulated in the form of messages. A simplistic solution to this problem is to broadcast all the relevant messages to all entities in the online game. The main drawback of this approach is its (lack of) scalability. As a solution, many communication reduction mechanisms have been proposed; among them two main approaches can be identified:

- **Filtering of interactions** based on their relevance (i.e., interest management, spheres of influence, data distribution management)
- **Frequency reduction of the interactions** (i.e., dead reckoning)

In both cases, the goal is to minimize the number of exchanged messages among nodes involved in the online game.

Interest Management

Interest management (Morse et al. 2006) is a technique based on interest expressions (IEs) that are used for implementing a filtering mechanism. The IE is usually based on location (or other application-specific) attributes and provides a way for each entity in the game to receive only the subset of information that is relevant for it. The information that is relevant for an entity is often referred to as its domain of interest (DOI).

In the years, many interest management schemes have been proposed with different communication models and filtering mechanisms. The aim of all such techniques is to reduce the number of messages that is transmitted over the network. This is accomplished by specifying in each receiver what type or class of messages is interested to. For example, an entity shall be interested in all the messages that are correlated to its sensing capabilities. This is called aura and it is modelled as a subspace in which the interactions between the entities occur. More specifically, the aura can be defined using different methods such as formulae, cells, polygons or extents. In case of mobile entities (such as avatars associated to a player in a game), their aura needs to be updated during the entities' movement. This aspect can introduce a relevant overhead in the interest management implementation.

An interest management implementation can be found in the high-level architecture (HLA) specification (IEEE 1516 Standard 2000). The so-called data distribution management (DDM) is responsible to manage the areas of interest in distributed simulations that are compliant with this standard. More in detail, the DDM services are responsible for sending events generated on update regions to a set of subscription regions. Each event in the simulation can publish data in specific update regions and subscribe to the events that are published in the subscription regions.

A different formalization of the interest management is called *spheres of influence* (Logan and Theodoropoulos 2001). In this case, it is assumed that different types of events have different spheres of influence within the shared state of the online game. The term "sphere" is used metaphorically and refers to the parts of the shared state that are directly affected by a specific instance of a given event type. Considering the spheres of influence, it is possible to filter the delivered messages but also allocate the entities composing the online game on the different parts of the execution architecture with the aim to reduce the amount of communication.

Dead Reckoning

The aim of dead reckoning techniques is to reduce the frequency of updates that need to be delivered to the entities in an online game, for example, the position of each avatar in the game environment (Wolf and Pantel 2002). Dead reckoning consists in estimating an avatar's current position based on a known starting point and its velocity. The basic idea is that using both the starting coordinates and velocity, it is possible to predict the position of the avatar with a given level of confidence. In this way, it is possible to reduce and delay the transmission of next messages embodying position updates. This permits to reduce the network traffic and to save the communication latency at the cost of (some level of) data consistency. The presence of data inconsistencies introduced by the dead reckoning mechanisms must be addressed each time a new update message is received. For example, unexpected jumps in the position of entities must be avoided using appropriate "smoothing" techniques.

Online Players: Engagement, Immersion, and Absorption Across Secondary Worlds

Ilaria Mariani
Department of Design, Politecnico di Milano, Milan, Italy

Synonyms

Gamers

Definition

Online players are players engaged in online gaming. They participate in a kind of games that are largely based on social interaction as their main form of play. Online players vicariously enter and interact with secondary worlds, their elements, inhabitants, and stories. Through their choices and activities, players affect the happenings occurring in such settings: they are in charge of taking action and making choices to make the game progress.

Secondary Worlds: Extra-Ordinary Spaces

Games can be framed as systems where players struggle against their fates, moving in a meaningful space of conflict with an uncertain outcome. If this definition describes games in general, it is not sufficient to explain the deepness reached by online games set in secondary worlds. They go further, engaging online players in challenging processes of immersion and absorption within persistent, evolving worlds where everything is deeply intertwingled.

Relying on the game studies literature, games are archetypically thought of as closed systems that bring to a form of activity, playing, that is timely, spatially, and socially separate from the everyday life and world. Since game-playing stands outside ordinary life, in the field it is typical to use the metaphor of the *magic circle* (Huizinga 1938). This concept conventionally identifies that *other space* where players operate, following specific formal rules. However, especially in the last decades, the borders of this definition have been pushed – and questioned by several authors. (The metaphorical idea of a magic circle was first introduced by Huizinga (1938), then reframed by Roger (1958) and later formalized by Salen and Zimmerman (2004) who contributed to its extensive dissemination. This article acknowledges both the critics (Taylor 2006; Malaby 2007; Consalvo 2009) and the defences (Zimmerman 2012; Stenros 2014) moved to the concept. Their discussion, although related, goes beyond the scope of this paper.).

From exponential computing power to the speed of our broadband connections, we are indeed living in years of ongoing technological transformation that is pressingly affecting the digital gaming field and the way players play, and the online gaming provides a clear mirror of such changes. From being a minor fraction within the broader business of interactive entertainment, online gaming flourished, turning into a major

market itself. According to the ESA Annual Report 2017, "53% of the most frequent gamers play multiplayer games, at least once a week, spending an average of 6 hours playing with others online." (data from the *2017 Essential Facts About the Computer and Video Game Industry* released by the Entertainment Software Association in April 2017). In parallel, significant efforts concern the development in terms of maintenance and expansion of the so-called *persistent worlds*, revealing a paramount attention towards massive multiplayer online games. (Fictional worlds that continue (or also simulate to continue) to exist and develop even when their players are not interacting with them (Bartle 2004). The term originally refers to virtual worlds, but is frequently used in relation to online fictional worlds (Adams 2010) as the ones of massively multiplayer online role-playing games and also pervasive games. Examples are: *World of Warcraft, Guild Wars, Destiny*, *Animal Crossing*.) And if games have indeed changed over time, with them it also changed players, the way of playing, and the culture of playing itself.

If the term online games generally refers to a technology rather than a genre per se, it is also true that connecting players together allowing multiplayer distributed games fed new ways of playing, foremost based on online social interaction as leading mechanic. Online games extended their gamespace, and hence players' gamespace: deeper and more interactive scenarios with growing agency in the players' hands, extended worlds to explore, where time is irreversible, distributed communities and people always available to play, 24/7. Unlike older media, these contemporary ways of playing keep asking players to enter the *liminal space* (Turner 1982), but also to transgress former boundaries. In doing so, screens and controllers assume the function of threshold objects (Murray 1997, 108) that welcome players to the realm of escapism and entertainment.

Matter-of-factly, addressing the topic of online players implies covering a substantial amount of topics. Tapping into the twists and turns of what it means playing online, the reasoning that follows takes the player's perspective and unfolds among the concepts of secondary world and its features, immersion, absorption, and their implications, socialization, and sense of belonging to dislocated but unified communities.

To unravel the knot, it is necessary to start from the foundations, and therefore outline the context wherein players move and explore its features. *Secondary worlds* is Tolkien's way of referring to those fictional, imaginary worlds that constitute the settings where stories can take place (Tolkien 1947). Albeit differing from the actual, real world – also called primary world – secondary worlds are self-consistent places with their own, unified sense (Wolf 2012). Regardless of their dimension that can range from being as small as an isolated village, or as big as a whole universe, these worlds have their own events and elements, characters and rules, duly intertwined and intermingled. Even if they are not "physical," secondary worlds are a significant matter to those players who engage and commit to them. They extend far beyond being mere game settings. To some players, certain fictional worlds become so stirring and engaging to appear "more real than reality itself." They are dynamic, complex models able to evolve and expand over time, engaging players in grasping their embedded and constitutive meanings. Indeed, their role is as key to sustain the fictional characters that live in these worlds and maintain their stories coherent, as much it is relevant to players, who can move and make experiences within those sound and consistent spaces.

In spite of being passive observers, indeed, online players are empowered to vicariously enter and interact with these worlds, their elements, inhabitants – NPCs behaving intelligently (artificial intelligence) and/or other online players (human intelligence) – and stories, affecting with their own choices and activities the happenings occurring in such settings. Taking the distance from traditional media, games as simulations (Murray 1997) recognize players' active role (Adams 2010; Lebowitz and Klug 2011): players participate in interactive representations (Frasca 2003) where they are in charge of taking action and making choices to make the game progress.

If in single-player online games the emotional engagement is mainly due to the meaningful

interaction with the narrative, the gameplay, or an holistic, balanced combination of the two of them, in multiplayer online games the engagement comes to a great extent from the interaction with the environment itself, as well as with other players, from the overall conflict and the competition against the others, and from the awareness of being part of a broader community actively committed to that world. These social activities, further expanded in the following, bring to relevant implications that are additional source of engagement, feeding sense of fulfilment and gratification (McGonigal 2011). Indeed, the formal structure of online words offers a large amount of quests and adventures, and affects the traditional use of game stories and of the narrative arch (Campbell 1949; Ryan 2009) typical of single-player games.

Hence, what is the typology of engagement players experience and seek when playing online games? So far, the rumination just tickled some of the points that make online games compelling forms of engagement.

From Immersion to Absorption: Being in *Another World*

Starting from the premise that human brain is "programmed to tune into stories with an intensity that can obliterate the world around us" (Murray 1997, 98), and discussing the unique properties and pleasures of digital environments, Murray (1997) introduces a concept that is as popular as "thick": that of *immersion*. It is the status of *suspension of disbelief* that occurs when the participation in a world reaches such a level of pleasure and intensity that the viewer/user/player gets transported – or submerged, to persist with the liquid metaphor – in the story, obliterating the outside world from her awareness. (The concept that originally addressed fictional representations (Murray 1997, 98) has later been proven to be valid for both fictional and nonfictional narrative texts (Ryan 2001, 93).) However, this does not mean that the player is rejecting the reality. Remaining conscious of indulging in a game of make-believe (Walton 1990), the attention is simply drawn to a secondary world that surrounds the player and taking over her. As a matter of fact, human beings can pay their attention in a limited way: focusing on one thing brings to pay less attention to something else (Holland 2009, 48; Wolf 2012). It means that while concentrating on the secondary world (its play or its story), less energy is available for focusing on the rest, namely the primary world. The player feels aligned with the story that is unfolding on the screen with such an intensity to outdo the surrounding world (Murray 1997). Hence, the more the player is into the secondary world and into the flow of its events (Csikszentmihalyi 1975, 1991), the less she is into the primary, real one; in consequence, the more captivating and overwhelming her experience of the *other* space becomes. As such, immersion is grounded on a simulative process, mental simulation (Currie and Ravenscroft 2002; Anolli and Mantovani 2011), that is also behind players' identification and projection in other roles (Gee 2003).

At this point, it is possible to assert that the edge is sharp, but there is no contradiction in saying that players get deeply immersed into another world, while retaining awareness of their surroundings. However, the reasoning goes further. McMahan (2003, 68) discerns between two different levels of involvement: at a diegetic level, it draws the player's condition of being "caught up" in the story of the game's fictional world; at a nondiegetic level it describes the intense interest of the player towards the game and its strategies. This reasoning provides room for investigating an additional concept that, digging into level of engagement, goes beyond immersion: that of *absorption*. Wolf (2012, 49) proposes an additional meaning to the word that is usually employed as a synonym of immersion itself, arguing that the concept of absorption differs from the previous because it is a two-way process. The one of *being absorbed*, or "pulled into" a world, and the one of *absorbing the world* itself, and being able to recall it when desired. The first process mainly relies on what discussed unpacking immersion; while the "way back" refers to the player's ability to "absorb" – and "grock" – the secondary world, "bringing it into mind, learning

or recalling its places, characters, events, and so on, constructing the world within the imagination the same way that that memory brings forth people, events, and objects when their name are mentioned" (Wolf 2012, 49). The paramount implication of this activity is that players, in doing so, not only extend the gamespace, but they also embed it, as part of their knowledge. And speaking of online games, the gamespace is often broader and richer than expected. Hence, playing their favorite online games, online players end up with gaining extended and often very detailed knowledge of secondary worlds.

Sociality, Community, and Epic Experiences

So far, the reasoning focused on the way online players relate to the secondary world from a theoretical perspective, rather than covering a topic that once again makes evident how these games blur the borders of the magic circle: player socialization as social expansion. The dynamics that characterize online games are rooted in their own social ecology. Mastery and exchange of knowledge are indeed conventions in gaming culture, and they are structured on the fundamental drivers of status, identity, and affiliation to a group. These drivers define interpersonal relations both within games and while interacting with other players as part of communities.

Player socialization is indeed a distinguishing trait of online games, and harnesses the human tendency to group and communicate. By their own nature, these games encourage social contact. Offering constant opportunities for social interaction, they promote the formation of social groupings, and in so doing they enhance the players' enjoyment of the experience. Far from creating single-player experiences, where every player is in a vacuum, multiplayer online games deliberately foster the gathering into self-organized or established groups, as teams, clans, or guilds (Herz 2002). To enhance the socialization as well as the exchange of information, online games usually present systems for real-time communication, depending on the game, online players can socialize via chat, voice or (less common) video chat systems.

As said, online games do not rest. They are always active, and as such are their players. In consequence, at every hour of the day, networks of individuals connected online cross geographical constrains and interact to play together.

Sociality also takes the shape of community. Communities are an undisputed, vibrant part of online game culture. It is well known that, from an anthropological perspective, playing feeds and elicits sense of belonging (Huizinga 1938). However, online games extend the sense of common identity. Moved by the presence of mutual, shared goals, and harnessing their rich knowledge, experience, tactical skills, and problem solving abilities, online players often participate in experiences that are *epic*. The term is one of the paramount concepts in gaming culture, being key in making game experiences as memorable and gratifying to provoke "shivers down the spine" (McGonigal 2011, 99). A working definition of epic is overcoming the limit of the ordinary to get to the extra-ordinary, "in size, scale and intensity" (McGonigal 2011, 98). Being part of *something epic* means contributing to something larger than themselves. McGonigal identifies three key ways in which games can be epic: creating epic context for actions, epic environments to explore, or epic projects. In each case, online players need to cooperate and carry out their efforts to achieve something otherwise unachievable – an example is *Halo*, and the collective efforts run by its online players.

As said, social interactions extend beyond grouping to take part in a game session. Spurred by common needs as self-identification, sense of belonging to a group that shares the same interests and passions, online players actively engage into virtual community. It is indeed common for players spending time and energy on system where they post, comment, feed discussions, share information and collaborate, as blogs, boards, or forums, in order to contribute and increase the knowledge of their community, the community of players.

A further form in which productive players show their being an engaged community is their active participation in building games themselves, from testing for bugs to creating new contents (Taylor 2007, 113). This attitude underlines a new ambiguity in the field, since it blurs line between creator and consumer.

Open Source 3D Printing, History of

Emily Peed[1] and Newton Lee[1,2]
[1]Institute for Education, Research, and Scholarships, Los Angeles, CA, USA
[2]Vincennes University, Vincennes, IN, USA

Synonyms

Additive Manufacturing; Fused Filament Fabrication (FFF); Rapid Manufacturing; Rapid Prototyping; Solid-Free Form Technology

Definitions

3D Printing is a form of manufacturing that adds small layers of materials together to form an object. This is in direct contrast to subtractive manufacturing, which cuts away at a material to form an object. Open source innovations have lowered the price of machinery and increased innovation in new markets.

Introduction

The market for 3D Printing has an open source variation, which began with the sharing of open designs, and further increased after key patents expired for the original technology. This entry goes through the open source innovations that have occurred since the first step in 2004 with the RepRap (Replicating Rapid-Prototyper) project. Since then, larger industry players and the DIY market has thrived as more have turned towards this technology.

While many are under the impression that the 3D printing spontaneously appeared onto the market around the mid-2000s, there is actually a deep history present that weaves together almost 30 years-worth of innovation, tinkering, and daydreams about the future. There were many emerging companies around the late 1980s, 1990s, and early 2000s within the 3D printing industry. With the origin of these innovations coming from countries such as Japan, France, Germany, and the USA, a surge of interest in a field then known as "Rapid Prototyping" got its start around 1984.

The inspirations and personal stories of the origins of the 3D printing industry are best served for another time. For the focus of this piece, we are going to zero in on the early 2000s where a form of open source 3D printing took hold.

To better understand this, it should be known that there are two major aspects to the 3D printing market. First, there is the high-end manufacturing spectrum of machines. These are high value, high quality machines typically utilized in a variety of large-scale industries such as aerospace, automotive, medical, manufacturing, and research facilities. These are machines created by some of the key originators of the technology, companies such as Stratasys or 3D Systems.

Second, there is the regular consumer market and the DIY market, which may not require the same level of functionality or quality to their prints. This second market has been largely driven by regular home consumer's demand for cheaper printers, primarily provided by the open source 3D printing movement. This does not mean that there isn't interest in the highest quality, it is just more often that it is not the highest priority.

The Open Source 3D Printing Movement Breaks Out

The Open Source 3D printing movement began to grow in the wake of open source designs.

Additionally, prices dropped further when key patents began to expire. Before these market innovations, machines previously cost up to $30,000 for what was considered a cheaper model. After the introduction of these designs, the prices were brought down to approximately $500. The most ubiquitous household name associated with the Open Source 3D printing movement is MakerBot. MakerBot can be thought of as the Kleenex of the 3D printing world (About n.d.). To be more specific, it is a name synonymous with the product but is not the only one. This is similar to when facial tissues are referred to generally as Kleenex when that is actually a brand name. These machines were originally based on open source designs and its rise has been ripe with controversy, as you will soon learn. However, this portion of the market and MakerBot itself stands on the shoulders of an unexpected project. Adrian Bowyer, a British Mathematician and Engineer, is credited with beginning the open source 3D printing movement. Previously studying geometric modeling and computation, Adrian Bowyer was one of the creators of the Bowyer-Watson algorithm for Voronoi diagrams. He also studied Biomimetics in self-copying and self-assembly engineering and smart hydrophilic-polymer gels using affinity interactions for the Department of Mechanical Engineering at Bath University. Dr. Bowyer conceived of the "RepRap" concept as an open source, self-replicating 3D printer as early as 2004 during his tenure (Dr Adrian Bowyer n.d.). After facing his own reluctance, he was pushed by his academic peers to pursue the idea.

RepRap stands for Replicating Rapid-Prototyper. The printer is configured so that it can properly duplicate most of the parts needed for another 3D printer, making 50% of its own parts as early as 2005, and when nuts and bolts are excluded it has recently been pushing 70% (All3DP 2016; About n.d.). Plans exist so that the future versions of the machine will even be able to inlay its own electric circuitry, making the project closer to the goal of a printer that can truly replicate itself (About n.d.). In 2009, using interchangeable heads, the RepRap 3D printer took steps towards that goal and began to make circuit boards with its utilization of plastic and conductive solder. Until machine capabilities evolve, the other parts necessary for total completion are chosen to be cheaply available in most places. Currently, Dr. Bowyer is retired from his tenure at the University of Bath but still heads the RepRap Ltd., which pursues further research surrounding the RepRap project.

These printers have gone through iterations named after people like Darwin, Mendel, and Huxley. Each of the machines were named after famous evolutionary biologists since the project is about replication and evolution (The Official History of the RepRap Project 2016). During their creation, some machines were even recognized for their uniqueness. The shape of the Mendel printer resembles a triangular prism rather than a traditional cube and received the Kartik M. Gada Humanitarian Innovation Prize from the Foresight Institute in 2010. It was also one of the first printers to integrate expiring technological patents within 3D printing.

The initial project has evolved and splintered off into many different areas. With different types of RepRap machines designed for different tasks, such as being able to switch between multiple colors, accommodate large-sized prints, been fitted into suitcases for portability, and has even spawned original concepts like the RecycleBot. The RecycleBot is a machine that turns plastic waste into usable filaments for 3D printers. Surely not the last of what this project inspires, the innovation left in its wake is admirable and is not even the most well-known.

The Most Famous RepRap

To understand the most famous RepRap machine, we will need to look at the company familiar to many as MakerBot. Winding the clock back to 2009, we find that the Cupcake CNC was introduced, or what will become to be known as the first MakerBot printer. These printers soon began to pop up among hacker and makerspaces, marking the rise of a company that would take a tragic comedy turn of events turning it from a darling of the open source world to scorned outsider in less

than 5 years. The rising popularity of the machines brought millions of dollars in venture capital funding, and with it competition.

After MakerBot enjoyed market dominance for a few years, a 3D printer called the TangiBot was released on Kickstarter in late 2012 and deemed a threat to the future of MakerBot, as the designs were essentially an improved design of their open sourced model (Benchoff 2016). Consequently, a month after the introduction of the TangiBot, the MakerBot 2 was released in 2012 and was markedly closed source. Open source champions that helped to found the company in early 2009, like Zachary Smith (AKA Hoeken), parted ways with the company following the break in their ideology. Previously being a creator of the RepRap Darwin 3D printer, he wrote a stanch blog entry and described the move as the ultimate betrayal. In the post, he describes how he is now even ashamed to have his name associated with the product (Smith 2012).

The hollow corporatization of the company continued and in 2013, Stratasys announced it would purchase MakerBot. Creating an ironic full circle of ideas, as Stratasys was actually the originator of the Fused Deposition Modeling (FDM) technology that the original open source RepRap and MakerBot systems were based on – called FreeForm Fabrication (FFF) in their open source counterparts. There was never a return to the glory for the brand, however, and over the last few years MakerBot sales slowly diminished and stagnated. Selling roughly 40,000 printers a year until 2015, where it dropped to approximately 18,000, and only 1421 in 2016 (Benchoff 2016). This could also be attributed the massive market saturation encountered, as even the professional version of RepRap, called RepRapPro, also shuttered its doors.

The MakerBot brand has struggled since and faced downsizing in terms of employees and locations, eventually closing all and outsourcing manufacturing to China. This reaction was partly viewed as the distaste left in the mouths of consumers knowing the origins of MakerBot, but mostly systematic errors on Stratasys's part in the creation of a "Smart Extruder" that was anything but. These miscalculations eventually led to a class action suit against Stratasys where investors state that the fifth generation of the printers were rushed, generated negative feedback, used misleading positive claims, caused numerous warranty claims, and returns of the product (Benchoff 2016). It was also an ill hand to play at the time as the market had become saturated in recent years with cheaper printers that were being created and funded on sites like Kickstarter at a rapid pace.

This was not the only controversy to daunt the company. MakerBot was also behind "Thingiverse," a website repository for 3D printer designs that was mutually accessible by everyone. The site flourished and many people turned to utilize it; however, under the leadership of Stratasys eerily similar applications for patents were filed that seemed to be based on designs uploaded onto the site. This created a row among creators and content managers, alongside denting the image of the platform. While Thingiverse is still going strong, platforms like YouMagine gained traction and steam through the ensuing conflict.

This fall from grace does not mean that there is not viability in the open source 3D printing movement, or even redemption. MakerBot has offered an experimental platform for users to interact with in 2017 for free, though it will never make a full return to its open source roots (Orf 2017).

It is important to note that the RepRap project opened the world of 3D printing up, enabled MakerBot to even have a beginning, and through its pursuits and influence enabled the desktop 3D printer to come to roost in many homes across the world.

Continuing the Drive of Innovation

The passion for this liberation of knowledge is no longer restricted to smaller companies or groups

of individuals seeking to create accessible knowledge for the masses. For example, Autodesk is a leader when it comes to many high end software used by gaming, animation, and many other industries. They are a software company that has turned hardware developer and has dedicated aspects of its core products to open source. The product is their Ember line of printers. They have even released the formulas for their resins.

The machine schematics and parts lists were shared under the Creative Commons Attribution ShareAlike license. The firmware was shared with a GNU GPL license. The printer is a Digital Light Processing (DLP) style printer, which makes it unique as most open source designs are FDM/FFF, as with RepRap. What Autodesk realized was that publishing the source files, parts list, and resin formulas for its product does not have to interfere with its ability to be profitable. The head of Autodesk's hardware group said:

> We're open sourcing our resin for a couple of reasons: We have an open approach, and encourage the use of 3rd-party materials in our printer... Autodesk is thinking differently about 3D printing, and sharing under a license reflects our commitment. Open sourcing our resin formulation is only the first step in the journey of opening our 3D printer and our Spark 3D printing platform. (Hurley 2015)

These examples of open source 3D printing technology do not capture the full scope that is represented. There are influential companies such as Lulzbot or the high-end Ultimaker that have carved out their own market niches. Countless projects on platforms like Kickstarter and projects created in garages around the world continue to change the face of this movement. There is more innovation waiting and the field is chipping away at other forms of popular 3D printing technology, especially as other key patents expire in other domains in 3D printing. It is important to note that there cannot be an expectation that another explosion of innovation such as what was viewed with the FDM technologies will occur again. The unique dynamics that attributed to the rapid onslaught of innovation for that style of printer will be hard to replicate. These are things such a few patents to overcome, simplistic design, a hungry market, and lower costs of entry and design.

Conclusion

There should be little doubt that the open source movement will continue to create innovations in its wake, while producing better products in the competition that it spawns. There is hope that 3D printing in the hands of the masses will create a better, stronger, more reliable technology as it becomes more mainstream and integral in our lives.

The economic, social, and societal impact could also be greatly underestimated. Let's look at a comparable technology. When computers were first invented they were hulking machines, taking up entire rooms, required punch cards, and held no graphically based user interface for most of its existence. The graphical interface and an underlying way to interact with the technology is important in the usability of computers and what attributes to its wide adoption. It has only been since the late 1970s and 1980s that these machines found there a way to the more common user. This step many years ago opened up a niche and has forever changed our economy, society, and world.

There is a similar path at play here. The time frame is still murky, but within the next few decades, the dismay that some currently show towards the potential of 3D printers will seem inconceivable. The software and ease of use are going to continue to evolve and bring more usability to these machines. Lessening the costs of these machines enables more research, faster development and overturn of prototypes, and the ability to learn as never before. The impact of this type of movement cannot be understated, and its fruition will be exciting to see.

Origin of Games

Hanno Hildmann[1] and Jule Hildmann[2]
[1]Departamento de Ingeníeria de Sistemas y Automatica, Av. Universidad, Universidad Carlos III de Madrid, Madrid, Spain
[2]The University of Edinburgh, Edinburgh, UK

Definition

Games are rule-based interactions. In the popular use – and for literally thousands of years – the term refers to playful activity. *Computer games* are all games that are played using a computer to display the board, generate events, provide other players to play with or, generally, for any other game relevant aspect.

Introduction

Playing and games are an essential part of human behavior, with a plethora of positive effects on the social and cognitive development of individuals.

Games have been played since the dawn of human civilization, and some have persisted through the most dramatic changes in society and environment. Games are seen to serve a range of purposes and have been described as being an integral part of society (Bell 1979), of teaching (Hildmann and Hirsch 2008; Smaldone et al. 2016), learning (Hildmann and Hildmann 2009a), and growing up (Miller et al. 2010).

The history of games easily fills entire books and a number of such books offer a detailed account, e.g., Tylor (1879); Murray (1952); Bell (1979); Miller et al. (2010), to name but a few. We know that games have been played for thousands of years (MacKenzie et al. 2004; Murray 1952), and – depending on your definition of what a game is – we can argue that they have been around for as long as we have recorded history. Computer games, in contrast, have only recently entered our culture (Hildmann and Hildmann 2012a, b), but their impact has been massive (cf. Jahn-Sudmann and Stockmann 2008). The rapid growth of

literature on computer games (e.g., Dillon 2016; Fox 2013) speaks to their continuously growing relevance.

Practitioners have argued for decades that games are – and that the playing of games is – culturally significant (Sutton-Smith 1986; Mechling 1987). As far as computer games (and the computer game industry) are concerned, they are by many considered an essential part of the software and entertainment industry (Saarikoski and Suominen 2009). Here we discuss the terminology of "game" and "play," the benefits of playing and the origins of games which brings us to the first computer games.

Play "n" Games

In the English language, games are "played," rather than "done" or "conducted" – yet play is a much wider concept than merely extending to games. In this entry, we will see the term "play" generally applicable to games, while emphasizing that playful behavior and experience is a continuum, and computer games and others can vary greatly between being highly engaging and joyful and being a dull training exercise thinly disguised by the label of "games."

The use of games for nonrecreational purposes, often referred to as *serious games*, is certainly not new and certainly not restricted to education (Puschel et al. 2010); *business games* have been proposed for research as early as the 1960s (Babb et al. 1966) and 1970s (Rowland and Gardner 1971). Games have been used to great success to train complex problem management (Pasin and Giroux 2011) problem solving abilities (Christoph 2006) as well as practical and reasoning skills (Pee 2011).

As discussed extensively in Hildmann (2013), games are also used as embodiment for psychological experiments (e.g., Rutledge et al. 2016). In fact, (computer) games themselves have been analyzed from a variety of perspectives, both negative (e.g., aggression, violence, or gender stereotyping) and positive (e.g., skills development, engagement, or motivation) (Connolly et al. 2008). Poorly devised educational games run a high risk of failing their intended purposes, especially when not taking the players' views and likes into consideration run a high risk of failing their intended purposes. Games in the context of this chapter are verbal, physical and/or virtual interactions governed by a set of rules between participants, i.e., *players* – or between a player and the environment – for the purpose of experiencing flow (Csikszentmihalyi 2009) and/or positive emotions.

Playing as an Essential Human Activity

Playing is an urge and activity inherent to humans – and other species (Bjorklund and Gardiner 2011; Pellis and Pellis 2011; Smith 2010). This suggests play to have a significant value for the individual development and evolutionary survival of those engaging in it. And indeed, a wealth of literature discusses the benefits perceived gained from participating in games and play.

In the literature, such as Pellegrini and Smith (2005) or Smith (2010), it is generally agreed on that different types of play are distinguished:

- *Object (manipulation), sensorimotor,* or *functional play* (such as e.g., shaking a rattle, building a tower with bricks) is shown to improve neurosensory maturation, body coordination, and mental representation of objects (Smith 2010).
- *Social contingency play* (Smith 2010).
- *Locomotor play* or *physical activity play* (e.g., running, chasing, swinging, pretending to be a superhero in action) is argued to support physical development of children, cognitive performance, and social organization (Pellegrini 2011).
- *Pretend* or *fantasy play* (e.g., moving wood blocks around like cars or planes, playing "mother-father-child" or "doctor and patient") exercises social patterns or "scripts," language and other cognitive skills, role-taking, and creative imagination (Smith 2010; Kavanaugh 2011).

- Physical activity play (e.g., rhythmic stereotypes/repetitive movements, exercise play) promotes neuromuscular maturation in infants, and control of specific motor patterns (Smith 2010). *Rough-and-tumble play* (e.g., play fighting, wrestling, jokingly kicking) is a subform of physical activity play and is argued to train the social brain to develop notions of fairness, competition versus cooperation, and a sense and strategies for dealing with ambiguous situations (Pellis and Pellis 2011).

The developmental benefits of playful behavior and social interactions have been well documented and discussed (cf. e.g., Smith 2010). According to psychological and sociological evidence, the playing of games has a crucial relevance for cognitive physical and social development – although the evidence-base around this is contested (Fagen 2011).

Of the six types of play suggested by e.g., Pellegrini and Smith (2005) or Smith (2010) (some of which are listed above), namely, *social contingency play*, *sensorimotor play*, *object (manipulation) play*, *language play*, *physical activity play*, and *fantasy* or *pretend play* the categories *social contingency,* and *fantasy/pretend play* apply to the bulk of computer games. *Language play* is represented by e.g., foreign language games, *physical play* has recently seen an immense interest from the gaming community, initially due to the release of the Wii and *object play* is found in games such as Minecraft.

The First Games

Few people will be familiar with the ancient *Royal Game of Ur* which was popular in Mesopotamia 4600 years ago (Green 2008) and thereby one of the oldest games on record. A game that has survived the test of time much better is *Chess*, which is considered to have originated in fifth- or sixth-century Persia and is thus more than 1400 years old (Shenk 2007). The ancient (according to Fairbairn (2004) 4000 years old) game of *Go* surpasses *Chess* in complexity and the two are said to be the only two games to survive *"the trial of centuries without any material change in the rules"* Lasker (1960). *Go* is another game that is by some considered to be *the oldest game of all* (Smith 1956), possibly being three times as old as *Chess* Lasker (1960), with its origins dated back to Wu, a vassal of the Chinese emperor Kieh Kwei (1818–1767 BC) (cf. Lasker 1960; Smith 1956). It is said to be of great value for the exercising of the brain (Smith 1956) and became played zealously by the Samurai. It was well known in China in around 1000 BC, as poems from that time confirm (Lasker 1960). In Japan, its social importance was significant and it had influence on many aspects of daily life; by 200 BC poetry and *Go* went hand in hand in Japan (Smith 1956). The game was opposed by Confucians, not only because of its addictive nature but because of its underlying philosophical thought that *all is change and nothing is permanent* (Shotwell 2003). The game heavily relies on the formation of patterns (Park 2008) and has many analogies to warfare; indeed Shotwell (2003) mentions the famous Sun Tzu (Giles 1974) and his book *"The Art of War"* (Tzu and Cleary 1988). Another ancient game mentioned in the literature is *Nim* (Jørgensen 2009), which is said to have originated in ancient China – but dates are hard to find (Spencer 1975; Jørgensen 2009). The reader will be familiar with the game from early childhood: players take turns in removing matchsticks/pebbles/etc. from a number of piles, and the player to take the last is the loser. There are a variety of rules and versions of the game, but they all can be related back to the same class of rules and settings.

Contrary to very complex board games of *Chess* and *Go*, computer programs playing games such as *Tic-Tac-Toe* or *Nim* can be programmed easily as there are known algorithms and winning strategies for them (Bouton 1902; Conway 2001). There has been a number of machines which were programmed to play against humans e.g., *"Nimatron"* in 1940 in the USA and *"Nimrod"* in 1951 in the UK (Jørgensen 2009),

"Nimbi" in 1954 in Finland as well as in Norway (Saarikoski and Suominen 2009).

Early Computer Games

The majority of the literature on video and computer games looks at them as objects and neglects to investigate the underlying technologies (Royer 2011) and their potential (Hildmann et al. 2009; Hildmann 2009). It does not help that there is no commonly agreed upon definition for the term *game*, and certainly among technology enthusiasts there is a certain degree of uncertainty as to where the boundaries lie between work and play, or, in this case, between game and application. One could argue that finding the faulty tube in an old computer system constitutes a game, however, that would admittedly be stretching the definition. Generally, there are various opinions on what constituted the first computer game, and, more importantly, who can claim credit to have invented or written it (the literature is not entirely consistent about dates itself, our reference publications, e.g., Deane et al. (2006), Egenfeldt-Nielsen et al. (2008), Jørgensen (2009), Nyitray (2011), and Saarikoski and Suominen (2009) differ in the exact years). For those that are fond of computer games, this will not be the most important aspect; chances are each reader will have their own memory of which game they played first and where. Commonly the game *Pong* is attributed the title of being the first-born by those not in the know, however, there are records of the game of *Checkers* being developed and *Tic-Tac-Toe* being implemented as early as 1951 (Jackson 2000; Egenfeldt-Nielsen et al. 2008, respectively). The game *Nim*, mentioned above, was studied extensively and programmed in a variety of implementations available to the public (Jørgensen 2009; Saarikoski and Suominen 2009; Deane et al. 2006) after 1940, notably the New York World's Fair in 1940 (Jørgensen 2009) or the Festival of Britain in London in 1951 (Saarikoski and Suominen 2009). This notwithstanding, Nyitray (2011) dates the first computer game to be played by the general public back to 1958 (October 18, 1958, at Brookhaven National Laboratory, USA, to be precise). Nyitray (2011) also pegs that game (*Tennis for Two*, by William A. Higinbotham) to be the first game to feature interactive control as well as motion on screen, which *Nim* clearly lacked. While available to the public (and very similar in a number of ways to the version of tennis offered by the modern day Wii), *Tennis for Two* did not receive wider attention and soon disappeared of the market and never was patented.

Another game frequently remembered as being one of the very first computer games (Jørgensen 2009) is *Spacewar!*, created by Steve Russell, Alan Kotok, Martin Graetz, and others at MIT (Lowood 2009; Nyitray 2011). That game, dating back to February 1962, was originally invented to showcase the PDP-1 computer and arguably drew on the experience Russel had gained through his earlier collaboration with Marvin Minsky and his early work in games. In the fall of 1970, Nolan K. Bushnell, Ted Dabney and Larry Bryan decided to form the company "Syzygy" and to design a commercial version (i.e., coin-operated) of *Spacewar!* However, in early 1972, they found out that this name was already in use by another California company. So, in June of that year, they founded a company by the name of Atari, which, like the other names they had considered (e.g., "Sente" and "Hanne"), is a term from of *Go* indicating that a stone is about to be captured (Wolf 2009).

Computer games have become the subject of a whole field of study (Hildmann and Hildmann 2009a, b), their influence in culture has become a relevant aspect for a number of disciplines (Wagner 2006). As stated in Bogost (2007), video games are computational artifacts, and their cultural importance might just be because of that, i.e., they have cultural meaning as computational artifacts; Mäyrä (2006) dates the period when information technology and social and cultural processes became entangled as the 1970s and 1980s and claims that games like *Pac-Man* and *Donkey Kong* were so much more than *just* games

like many games before them. Computer games in that time (just like they do today) provide training and expertise in a medium (Hildmann et al. 2010; Hildmann and Hildmann 2011) that has increasingly become a central part of today's first world civilization. (Sutton-Smith 1986) observes that adaption occurs when there is something to adapt to, and conjectures that computer games are the response to the need to adapt to the computer. They might not have been invented because of this need, but they have found incredibly wide acceptance because of it. The importance of adapting to the computer is compared to adapting to the printing press in the sixteenth century (Sutton-Smith 1986).

Further Reading Recommendations

For a more detailed account of the history of computer games, the reader is referred to, e.g., Dillon (2016) or Purcaru et al. (2014). Luce and Raïffa (1989) discusses the decision-making in games. The use of games in a serious context is described in, e.g., Moseley and Whitton (2013), Hildmann (2010), or Gass (1993) and in, e.g., Ma et al. (2012) in the context of computer games. For theoretical work on game theory, the reader is referred to the standard literature in the field, e.g., Osborne and Rubenstein (1994), Davis (1997), and Binmore (2007). While there is an ever increasing amount of literature on the design and implementation of computer games, Smed and Hakonen (2017) and Günzel et al. (2010) are a good start.

Artificial reality; Simulated environment; Simulations; Virtual reality

Definitions

Virtual reality is the experience of an artificial environment simulated by a computer. The environment is provided through sensory stimuli such as sights, sound, vibration, and even smells. Interactive hardware and software create a realistic and immersive simulation, often in a three-dimensional environment to provide a more life-like experience.

Introduction

Virtual reality (VR) technology has been around for much longer than most individuals realize. In this article, we will go through the history of VR from the beginning to the more recent accomplishments.

The History of Virtual Reality

Historically speaking, we have been attempting to create experiences that put users into virtual scenes for longer than we have had electricity. Across the late eighteenth and nineteenth centuries, the panorama was patented by the Scottish Portraitist Robert Barker in 1787, where an exhibited painting was placed on a 360-degree view, circular canvas which surrounded the

viewer (Ford 2017). They essentially entered a building that was created to house an artwork that the individuals could walk through and experience. In the 1700's, this was as virtual as it could get. Virtual reality technology could be really said to have some of its foundational roots in the 1800s, specifically with the stereoscope invented in 1839. This evolved into the View-Master, patented in 1939 and is still a popular toy today. However, this industry takes many more decades before it begins to resemble what we recognize with systems like the Oculus Rift today but still far earlier than some may realize.

In 1929, Edward Link created the "Link Trainer" on a design that he later patented in 1931 (History of Virtual Reality 2016). It was an electromechanical flight simulator that encapsulated the individual into a replica cockpit. It had motors to control a rudder, pitching, and rolling of a craft. The machine mimicked turbulence and other disturbances. During WWII, 500,000 pilots improved their skills by logging hours of initial training on 10,000 "Blue Box" Link Trainer machines. Later, the Sensorama was created in the mid-1950s by Morton Heilig, a cinematographer that patented the device later in 1962. This device had stereo speakers, a stereoscopic 3D display, fans, smell generators, and a vibrating chair. The Sensorama had six short films that were created by Morton Heilig himself.

In the 1960s and 1970s, there was a slurry of inventions that are worthy of noting. These include a continuation of Morton Heilig's work within a device called the Telesphere Mask in 1960, which was a head mounted display that significantly moved us toward what is familiar today (History Of Virtual Reality n.d.). More attention was beginning to be paid as a pair of engineers from Philco Corporation, Charles Comeau and James Bryan, as they created the Headsight in 1961. It was an incorporated system that had a screen for each eye and a motion tracking system. It was originally developed for immersive, remote viewing of dangerous situations by the military. Ultimately meant to move with the body and designed to allow the user to look around the environment more naturally; however, it lacked the traditionaal on-board computer image generation hardware and software popular today. This limited its applications in the familiar areas of video games or simulations.

The 1960s also saw the writing of the Ultimate Display concept by Ivan Sutherland; his design housed a computer-generated virtual world that was maintained in real time. The user had the ability to interact with objects in the virtual world in a realistic way and augmented 3D sound and tactile feedback. The 1965 paper laid the foundation for concepts that represent the core blueprint for VR today – such as goals of creating an experience which totally immerses the user as it evolves over time. This is happening already, as virtual reality of today will eventually unfurl into immersive reality. This will be possible in the future of Brain Computer Interface (BCI) devices and experiences in the future.

The steps it has taken to get to this rudimentary version of immersive experience is traced through a history of machines so cumbersome and heavy that a series of wires was necessary to support them during play. Without them, there could be no hope for the average user to be strong enough to even use the systems. This was true for the Sword of Damocles, created by Ivan Sutherland in 1968. It was only capable of primitive gameplay through wireframe rooms and objects. The 1960s ended with Myron Krueger, a virtual reality computer artist, who developed a series of experiences that he coined under the term "artificial reality," which was when a computer-generated environment creates responses from people and enabled individuals to communicate with each other in these environments.

"Virtual reality" received its official title in the 1980s and began to be recognized as a field of study. This occurred when Jaron Lanier, founder of the Visual Programming Lab (VPL), popularized the term virtual reality through his company when they developed a range of gear including the Dataglove and the Eyephone head mounted

display, which were major developments for a field of study called haptics. These types of systems were even used by NASA in a device called Virtual Interface Environment Workstation (VIEW), which was a head mounted display that utilized the Dataglove and other systems to provide more integration for the user (Rosson 2014).

The 1990s popularized virtual reality with the public. It was through a series of games created by Virtuality Group, whose machines enabled individuals to interact with VR goggles, video games, and immersive stereoscopic 3D visuals that even enables multiple players. Then came the Lawnmower Man movie in 1992, which the Director Brett Leonard admitted was inspired by some of the equipment coming from VPL research labs. Major players like SEGA even attempted to get into the market, with an amazing prototype that they were never able to bring to the floor – this set the stage for the true nature of the complexities of making cheaply accessible virtual reality systems.

This challenge culminated in the Nintendo Virtual Boy of 1995, it was a red and black display game system that lacked software support and a comfortable way of playing. It was discontinued a year after production and virtual reality stayed in the domains of films like the Matrix. It wasn't until the 2010s that virtual reality became a true household phenomenon, primarily with the Rift in 2012– 2014 and easily accessible cellphone to virtual reality converters found in most chain stores – if not better console systems within the electronics department.

According to Business Insider, the virtual reality/augmented reality market is projected to hover over $162 billion in 2020 (Intelligence 2016). This rapid growth is due to advances in display technology, miniaturization of electronics, and the increasing power of small devices. Within the next few decades as the technology permeates, we will see it grow in capability toward more complex technology such as immersive reality. A pursuit that has been hundreds of years in the making.

> The study of intelligence, once dominated by biologists, has for decades been a focus for computer scientists. (Kitano 2007)

Synonyms

Artificial intelligence is a wide term, often used synonymously with the terms *computational intelligence* and *machine intelligence*. It is abbreviated as *AI* and today is used by the media to refer to any remotely clever program.

Definition

Intelligence, a term which defies a unified definition, is one of the most unique human traits. *Artificial intelligence* is the reproduction of any such behavior through the programming of a machine. This section aims to illustrate the difficulty of defining the very term artificial intelligence.

Background

The term *artificial intelligence* (AI) originates from a workshop held in 1956 at Dartmouth College, New Hampshire (Brooks 2001), but its founding works predate this (Waldrop 1984b). Among these works is Alan Turing's article on "Computing Machinery and Intelligence" (Turing 1950) which opens with the question *Can machines think?*, as are, of course, the works of the ancient philosophers who pondered the questions of intelligence, rationality, and mind. The works of, e.g., Aristotle (on formal logic), Leibniz (on binary numbers and on symbolic thought), Boole (on algebra), and Babbage (on analytical engines) can all be seen as contributing factors to the field of artificial intelligence (Wang et al. 2016). Simon (1977) claimed that "[w]e are now in the early stages of a revolution in processing information that shows every sign of being as fundamental as the earlier energy revolution," but after the initial euphoria in computing science, the promised progress in the field of *artificial intelligence* has come slower than expected. In the early years, the challenges that came with the field were underestimated by experts such as Herbert Simon, who famously prophesied in 1957 that "a computer [will] be the World Chess Champion before 1967" (Hsu et al. 1995). More recent predictions (Pearson 2008), while acknowledging the failure of the field to live up to the optimistic promises of early proponents (such as Alan Turing, John McCarthy, Marvin Minsky, Allen Newell, and Herbert Simon (Brooks 2010), see below), are, however, confident that the emergence of conscious and intelligent machines is imminent. Kurzweil (2008) repeatedly predicted machine intelligence to surpass human intelligence by 2050 (Landwehr 2008). The current resurgence of artificial intelligence, which to a great extent can be attributed to advances in computing power (which in turn enabled new approaches and algorithms), led to somewhat of a hype. This hype is fueled in part by the lack of nuance when discussing the concept of artificial intelligence.

This sections draws a picture of AI that, contrary to many contemporary articles, discusses key publications and people which provided the basis of modern artificial intelligence and influenced advances in the field to this day. We attempt to give the reader an understanding of the different schools within the topic, such as the *symbolic* vs. *sub-symbolic* approach and *strong* versus *weak* AI, and introduce some of the ethical considerations since these play an increasingly important role as AI becomes a pervasive technology.

Symbolic Versus Non-symbolic AI

In their paper "Computer Science as Empirical Inquiry: Symbols and Search," Newell and Simon (1976) postulated that "[a] physical symbol system has the necessary and sufficient means for general intelligent action." Symbolic AI is based on the idea that a symbol system is a fundamental requirement for intelligence and that machines can be intelligent because they can be designed to operate a sufficiently adequate symbol system. The counterview is of course that information and concepts are not necessarily represented as symbols but instead as signals, which are processed in massive numbers and generate meaning through coexistence with other signals. Symbolic AI uses logic, rule-based, and expert systems, while non- or sub-symbolic approaches are embodied by artificial neural networks or stochastic approaches.

Early proponents of the latter were, for example, Rodney Brooks who in "Elephants don't play

chess" (Brooks 1990) claimed that "the world is its own best model. It is always exactly up to date. It always has every detail there is to be known. The trick is to sense it appropriately and often enough." Currently, non-symbolic approaches account for the majority of advances in the field of AI reported in the mainstream media. This is due to the fact that many of the recent breakthroughs are based on neural networks. In the past, however, symbolic approaches made the headlines more often though, e.g., Mycin (Shortliffe 2012), an expert system for the diagnosis of infectious diseases, or ELIZA (Weizenbaum 1966), the first "chat bot" which was a simulation of a psychotherapist.

Strong Versus Weak AI

Another view on the world of artificial intelligence is through the dichotomy of strong versus weak AI. Weak AI makes no claims to truly implement intelligence and instead only talks about machines that implement very specific functions. Strong AI in contrast talks about *true* intelligence and about machines actually having a mind, just like humans. All current systems are weak AI systems as they are not making use of a general approach but are always purpose-built. A similar and somewhat less contentious view is to divide the field into engineers, who "are trying to get their programs to do smart things, by whatever means they can," and scientists, who "are after a general theory of intelligence, both human and machine" (Waldrop 1984b).

The question really is whether mankind is ready to accept the notion of machine intelligence. As Weizenbaum (1972b) illustrates, scientific insights gained have, throughout time, often result in humiliation. Understandably so, for as one learns the reason behind certain phenomena, one will have to revise the explanations previously adapted for them. The examples given are the classic ones, which have then (and in some cases still do today) been ridiculed and fanatically argued against: Galileo for challenging the notion of earth being the center of the universe; Darwin for providing an alternative – and rational as much as plausible – answer to why things in nature seem so well *designed*; and Freud for shattering the illusion of rationality. The more mathematically inclined reader might want to add Kurt Gödel, for proving Peano arithmetic (Shankar 1994) to be incomplete and thereby single-handedly throwing mathematics into a crisis of faith (cf. Wang 1997; Hawking 2007).

Intelligence is often considered a unique thing, something that, for religious or philosophical reasons, sets humans aside from anything else in the universe. Creating it artificially is to many an attack on the very foundations of their view on the *self* and the universe. Instead of raising machines to the level of intelligence, we are much more likely to reduce the notion of our own intelligence to, e.g., some emergent property of the complex system that is our brain. Independent of the fact that philosophy has long since chipped away at core concepts such as the idea of having a *free will* (Smith 2011), the *rationality* of our actions, the emotion *love*, and, ultimately, the notion of *consciousness*, accepting the artificial creation of intelligence in machines would cause a major crisis of faith to many. In the end, the jury is still out on whether artificial intelligence will ever be "truly" intelligent or if machines can have a mind. However, independent of what the answer will turn out to be, AI is very real, and its ethical implications need to be discussed.

Ethical Considerations

As the use of AI in everyday life becomes more ubiquitous, questions about ethical considerations need to be asked. These questions range from implications on the workforce (e.g., the loss of many blue-collar jobs) over responsibilities of actions of AI systems (e.g., accidents by self-driving cars) and bias due to skewed training sets (e.g., cheaper mortgages for Caucasians) to the question whether certain systems that *can* be built *should* also necessarily be built (such as autonomously operating weaponized drones). Most current AI systems are *decision-support* systems, rather than *decision-making* systems. This implies that the ultimate responsibility for

the actions taken lies with the human. We are now at a stage where such intelligent systems perform near or above human level. However, for decision support systems, the ultimate responsibility lies with the human, but the responsibilities for the actions of such systems have yet to be decided.

Obvious examples of this conundrum are about the use of autonomous vehicles, where decisions about life and death of passenger and passersby might have to be taken. These discussions appear more regularly now, with heads of the largest high-tech firms publicly arguing for or against the threat that AI, especially when combined with networked machines and robots, can that AI can pose, especially [. . .] machines and robots. These discussions have been ongoing for a while.

For example, Weizenbaum (1972b) and Wiener (1960) wrote on the moral and ethical issues of AI and allowing computers to make decisions; the latter being criticized by Samuel (1960) and the former by Coles (1972). In the end Weizenbaum rebuts (Weizenbaum 1972a) the argument by emphasizing again the dilemma of this period, i.e., the question on the responsibility of the researcher to consider what his research does and the issue of the *common man* meddling, through elected politics, with things outside his intellectual regime of competence. As far as the individual's responsibility is concerned, however, the common *man* (or, as in this case, woman) seems to agree with him (Holmes 1973). The above recounted string of statements and attacks thereon, followed by rebuttals and counter-attacks, while quite amusing to read, instills the image of the research community in the 1970s and 1980s being childlike and simple (which, given the topics discussed, seems ironic).

Application Areas

As Waltz and Buchanan (2009) point out, from their earliest days computers were used to automate calculations according to predefined instructions. Buchanan et al. (1968), working with Edward A Feigenbaum, created DENDRAL, which was among the first systems that would attempt to go beyond this and effectively *interpret* data, instead of simply performing calculations on it. Leveraging the potential of greatly sped up calculations in combination with large collections of expert knowledge (collected painstakingly from human experts), such *expert systems* became one of the dominant areas of AI at the time. With increasing data generation capability naturally comes the need for systems that can process these growing amounts of data. King et al. (2004) argue that without automation we simply lack the ability to analyze all the data we generate and suggest going further: King et al. (2009) report on an entirely automated biology lab where machines perform the experiment design and implementation, collect and interpret the data, and use the latter to inform the former. Schmidt and Lipson (2009) discuss automating the process of conjecturing and verifying analytical natural laws in the field of mathematics and physics. However, the advent of this brave new world where machines conceive entirely new ideas fit to spark a scientific revolution is not undisputed. Anderson and Abrahams (2009), for example, remind us that according to Kuhn (1962) there is more to science than the generation of new knowledge *within* the boundaries of existing beliefs and that the rare, but occasional *paradigm shifts* that occur within a field are the milestones along which advances in sciences are measured. Whether machines can match humans in their ability to *think outside the box* remains to be seen.

Today, applications of artificial intelligence techniques can be found in a large number of fields (Hildmann and Crowe 2011). Examples cover virtually all areas of scientific investigation, ranging from the autonomous discovery of laws in natural sciences such as physics (Schmidt and Lipson 2009) over the interpretation of mass spectra in cell biology and chemistry (Yates 2011) to mapping the synaptic connections of neurons to neuronal functions in neuroscience (Seung 2011). AI is also used in applied psychology and game-based learning where serious games are driven by AI players specifically designed to create game experiences tailored for individual human players (Hildmann and Hildmann 2012a, b). In addition, commercial applications for AI are equally pervasive with, e.g., the movie

industry using AI techniques to create and simulate entire physical environments and simulate lighting conditions and lighting effects in animated movies (Lewinski 2011).

Landmark Publications

With a field which spans multiple research areas and is as diverse as artificial intelligence is, today it is difficult to compile a list of landmark publications that does justice to all the advances and seminal contributions. While this is not a complete list by any means, the following papers certainly deserve to be included: "On Computable Numbers, with an Application to the Entscheidungsproblem" (Turing 1936 – proof of the decision problem that there is no algorithm to always decide whether a formal statement is true in a system), "Computing Machinery and Intelligence" (Turing 1950 – introduction of the Turing test), "A Behavioral Model of Rational Choice" (Simon 1955 – rational behavior must be compatible with information access and computational capacity), "Computer Simulation of Human Thinking" (Newell and Simon 1961 – argues that human behavior can be explained using natural sciences and laws alone), "GPS: A Program that Simulates Human Thought" (Newell and Simon 1963 – introduces the General Problem Solver, a computer program that replicates human thinking), "Some Philosophical Problems from the Standpoint of Artificial Intelligence" (Mccarthy and Hayes 1969 – introduces the frame problem, how to describe the world using logic without adding large numbers of (obvious) statements), "Computer Science as Empirical Inquiry: Symbols and Search" (Newell and Simon 1976 – poses the physical systems hypothesis that states that physical symbol systems have necessary and sufficient means for intelligent behavior), "What Computers Mean for Man and Society" (Simon 1977 – discusses predictions around computers and artificial intelligence), and "Machines Who Think" (McCorduck 1979 – one of the first detailed discussions on the history of AI, based on interviews with key figures).

Key Figures

Today the field of artificial intelligence transcends almost all walks of life. It is found in anything from public transport to research into theoretical mathematics and the finance markets. Compiling a comprehensive list of key figures is impossible; at best an entire book might suffice to list key figures in all the subfields now belonging to AI. The select few listed below are meant to be representatives, in part chosen because their works are referenced substantially in this encyclopedia. They are people that have led and inspired; their names represent entire fields, research groups, and institutions.

Allan Turing (*1912–†1954)

Allan Turing's contribution to artificial intelligence and the field of computing science is repeatedly mentioned below. He is famously known for both the *Turing machine* (Turing 1936) and the *Turing test* (Turing 1950); his importance to the field is also reflected in the fact that the *ACM A.M. Turing Award* (http://awards.acm.org) – computer science's highest honor (Campbell-Kelly 2007) – bears his name. As early as 1947, Alan Turing described the human brain as a "digital computing machine" (Turing 1995). He also postulated that the assumption of infallibility (in the context of machines) excluded the ability to exhibit intelligent behavior, though the reverse phrasing is probably closer to what he meant, namely, that intelligent machines cannot be infallible.

Among Turing's best known achievements is the proof that there are formal limits to computation, which he famously did by showing that the *halting problem* is undecidable (Turing 1936). Already in the 1940s, Turing maintained that "a computer could play 'very good chess' if 'occasional serious mistakes' were allowed"; his argument being that by allowing for mistakes "Gödel's incompleteness theorem becomes irrelevant" (Hodges 2007).

Alan Turing devised a theoretical machine (known as the *Turing machine*) that could read and write from an infinite tape, move along this tape to any position on it, and execute a finite

set of instructions. He then showed that such a machine could be fed the description of such a machine and execute it faithfully. This machine is, in essence, the idea of a programmable machine and as such describes today's computer hardware. The instructions fed to such a machine are, in turn, describing today's computer software. Therefore, by describing his so-called Universal Touring Machine, Alan Turing described the computer of today (Strawn 2014). Furthermore, *Turing completeness* and the *Church-Turing computability* are also landmark contributions to theoretical computer science. In addition to being maybe the most famous representative of the field of AI, Turing published landmark papers in biology and played an integral role in breaking codes during World War II.

Tragically and despite having played an integral role in saving Great Britain in World War II from fascist Germany, the UK government turned on him for having relations with another man. Given the choice between the public humiliation of a prison sentence and chemical castration, he chose the latter. Subsequently, as a direct result of this treatment, Turing took his own life on June 7, 1954, at the age of 41 (Strawn 2014). It has taken the UK government 65 years to even apologize for this injustice (in September 2009, British Prime Minister Gordon Brown made an official public apology on behalf of the British government for *the appalling way [Turing] was treated.* On Christmas Eve 2013, Queen Elizabeth pardoned Turing posthumously (Strawn 2014)), and still today, many articles written on the occasion of his 100th birthday (e.g., Severance 2012; Lipton 2012) fail to even mention the reasons that led to his death.

Marvin Minsky (*1927–†2016)

Marvin Minsky, winner of the 1969 ACM A.M. Turing Award, is generally considered one of the pioneers of artificial intelligence and robotics (Hassler 2016). He believed that machines can be intelligent, that they can match human performances, and that this would happen in his lifetime.

Together with John McCarthy, Marvin Minsky founded MIT's AI lab in 1957 (Hassler 2016). Together with Seymour Papert, he conceived the *Society of Mind* and developed this speculative cognitive science and philosophy theory (Strawn and Strawn 2016) from the early 1970s onward. He later published a seminal book by the same title (Minsky 1988). He basically postulated that the human mind is comprised of a collective of agents for various different tasks and challenges and that it is in fact the collective (the *society* of these agents) that makes up our mind (Strawn and Strawn 2016).

In 1972, together with Seymour Papert, he published the highly controversial book *Perceptrons: An Introduction to Computational Geometry* (Minsky and Papert 1972). In it the authors show that certain neural networks are limited in computational power and that there are certain things they cannot learn. Whether intentionally or due to being misunderstood by the field is still a debate today, but as a result of this book, funding and support for neural networks (i.e., for non-symbolic AI) dried up for roughly a decade (Olazaran 1996; Strawn and Strawn 2016). This created a mind-set that diverted efforts and support from the field and which might have persisted until the rather recent success and victory march of Deep Learning, which might very well have played a crucial part in changing how artificial intelligence is perceived by the public. For quite a while there was the widespread notion of a *winter of AI*, representing the sentiment that the promises made had all failed, but the return of neural networks to advance the field of AI and leap-frog to what is considered by many *ahead of its time* certainly demonstrates the outstanding performance potential of artificial neural networks.

John McCarthy (*1927–†2011)

John McCarthy, winner of the 1971 ACM A.M. Turing Award, is arguably the "father" of artificial intelligence as it was him who coined the term *artificial intelligence* in 1955 when proposing the workshop held in 1956 at Dartmouth College, New Hampshire (Brooks 2001). Together with Marvin Minsky he founded MIT's AI lab in 1957 and 5 years later, in 1963, Stanford's AI lab. One of his great achievements

was the development of the logic-based programming language LISP which was proposed by him in 1957 (McCarthy 1960). This puts him in the camp of symbolic AI, and he was an important influence in the use of logic in artificial intelligence.

He was also thought to have developed the so-called alpha-beta pruning algorithm (Knuth and Moore 1975) that allowed computer to more efficiently play games such as chess. However, his influence was arguably greater in the philosophical discussions around intelligence and whether machines can be truly intelligent (McCarthy 1959; Mccarthy and Hayes 1969). He believed that "It's difficult to be rigorous about whether a machine really 'knows', 'thinks', etc., because we're hard put to define these things. We understand human mental processes only slightly better than a fish understands swimming" (Mccarthy 1983).

Herbert Simon (*1916–†2001)

Herbert Simon, winner of the 1975 ACM A.M. Turing Award as well as the *Nobel Memorial Prize in Economic Sciences* in 1978, has been called by some a *father of artificial intelligence* (http://www.post-gazette.com/obituaries/20010210simon2.asp). Simon (1955) explored and defined the concept of rational choice for *organisms, including man*. The definitions and the model he provides are, however, quite discrete and he makes repeatedly reference to computers. In a publication titled "Computer Simulation of Human Thinking," Newell and Simon (1961) argue that we can reduce the observed human behavior to chemical and physical mechanisms.

Simon (1977) claims that any limits to computer intelligence are also limits to human intelligence and thus that there is – in theory – nothing that stands between machines achieving human-like intelligence. He points out that the question whether it *can* be done might not be what is holding us back. Instead he identifies the fundamental question to be a threating one (to many people) and one of a more philosophical nature altogether: what does it mean, if it can be done? As Darwin's and Copernicus' ideas before, the concept of *artificial* intelligence challenges the uniqueness of humans, in this case, the uniqueness of *human* intelligence, that is, it questions our position in the model of reality we entertain. After all, if machines can be intelligent (and if we are only the product of long series of modifications aiming to adapt to changes in our environment, which also happens *not* to be the center of the universe), what then makes us any more significant than the rest of the matter in the universe? How can we justify our sense of self?

In Simon (1977) he states the belief that *it is entirely possible for programs to modify themselves - that is, to learn*. Consequently, his follow-up questions focus on the extent to which human behavior can be simulated by a computer and which of our activities computers should be allowed to replace. He predicted that we *are now in the early stages of a revolution in processing information that shows every sign of being as fundamental as the earlier energy revolution. Perhaps we should call it the Third Information Revolution. (The first produced written language, and the second the printed book.)*. Simon even considered using computer simulations to explore the human mind by psychological research (Simon 1977).

Edward A Feigenbaum (*1963–)

Edward A Feigenbaum is the winner of the 1994 ACM A.M. Turing Award (jointly with that of Raj Reddy), for "pioneering the design and construction of largescale artificial intelligence systems, demonstrating the practical importance and potential commercial impact of artificial intelligence technology." In his dissertation, completed in 1959 under the supervision of Herbert Simon, he developed one of the earliest computer models for human learning.

In the late 1960s (Waldrop 1984a), he developed Heuristic DENDRAL (Buchanan et al. 1968; Yates III 2011; Waltz and Buchanan 2009), a program used to investigate chemical structures at a professional level and is considered as one of the (if not *the*) *father of expert systems*. His work on knowledge engineering and expert systems has affected almost everybody, be it in the form of Microsoft's dreaded paper-clip wizard

assistant or any other knowledge database interface. His work led to a boom in expert systems and caused increased interest – and investment – in the field of AI.

One of his key areas of interest was heuristics, i.e., means to approach and find good solutions to computationally hard problems (as opposed to deterministically deriving the best possible solution). In today's increasingly connected and complex world, heuristics may be a load-bearing pillar that drives enterprises in areas ranging from resource allocation over scheduling to Big Data and the Internet of Things. Though less known, his legacy is everywhere.

Norbert Wiener (*1894–†1964)

Norbert Wiener was an early protagonist of stochastic processes, nominated (alongside Shannon) for the 1959 Nobel Prize in Physics. He was full professor of mathematics at MIT, and the *Norbert Wiener Prize in Applied Mathematics* is named after him. Norbert Wiener is considered to be the founder of *modern* cybernetics (Bardis 1965) and worked on important contributions and theories in the fields of robotics and automation.

He is considered as a key figure in the field of AI here for a number of reasons, among which is the fact that he was involved in the building of the cognitive science team at MIT which would go on to make landmark contributions to the fields of computer science and artificial intelligence. He collaborated with von Neumann on models for neurons and like Shannon worked on early investigations into information theory.

Wiener (1960) challenged an opinion he felt was common with *the man in the street* (and, as pointed out by Samuel (1960), also by some men of science): the assumption that machines cannot possess or exhibit originality. He did in fact believe that the opposite was possible, i.e., that machines can possess originality (Samuel (1960)). He was not alone in his views, as contemporaries such as Johnson and Kobler (1962) shared his beliefs. In this paper he elaborates on game-playing machines, specifically mentioning *chess*.

Final Thoughts

It is clear that a complex and controversial topic like artificial intelligence that touches onto almost any domain and influences many of today's technological accomplishments cannot be adequately described in a few pages. Instead of aiming for an incomplete overview, we have tried to provide the reader with a sense of history and the references to go on an expedition into the origins of artificial intelligence, the mind, and ultimately the question of what it means to be human.

Overview of Virtual Ambisonic Systems

Michael Mcloughlin
Centre for Digital Music,
Queen Mary University of London, London, UK

Synonyms

Ambisonic binaural rendering

Definition

A surround sound method that combines binaural audio reproduction methods with ambisonic surround sound technology.

Introduction

Virtual ambisonics is a method that combines binaural audio simulation and the surround sound reproduction method known as ambisonics. This entry gives an overview of the basic psychoacoustic theories behind binaural hearing, methods to simulate binaural hearing, and the issues that may arise from these simulation methods. This is followed by a brief description of ambisonics and how it can be combined with binaural audio to create virtual ambisonics.

Binaural Hearing

Binaural hearing describes how humans are able to locate a sound source in three dimensions using two ears. A listener can identify sound sources based on the difference between the time of arrival (interaural time differences or IDT) (Wightman and Kistler 1992) or the difference in intensity levels (interaural level difference or ILD) (Hartmann and Constan 2002). Listeners also identify the location of sound sources due to filtering effect caused by the shape of the pinnae (Hofman et al. 1998). Listeners use head movements in order remove ambiguity in regard to the location of the sound source (Perrett and Noble 1997). Non-biological cues are also involved, with perceived source distance being associated with how reverberant the sound source is (the precedence effect) (Litovsky et al. 1999).

Head-Related Impulse Responses and Head-Related Transfer Functions

Due to complexity and nonlinearity of human hearing, it is necessary to use head-related impulse response (HRIR) to capture the

characteristics of human hearing. A simple HRIR can be captured using a binaural dummy head with omnidirectional microphones placed in each ear of the dummy. The dummy head is placed inside an anechoic chamber, and an impulse response or sine wave sweep is played through a loudspeaker and recorded via the dummy head. This can be used to generate head-related transfer functions (Jot et al. 1998; Hammershoi 1996; Hammershoi and Moller 2005). A head-related transfer function (HRTF) is what is obtained after carrying out a Fourier transform of a HRIR. The HRTF describes the filtering of a sound source before it reaches the eardrum.

In order to synthesize a virtual sound source, a HRIR for the left and right ear is convolved with a sound source that was recorded using an omnidirectional microphone in an anechoic chamber (Jot et al. 1998). This convolved output is then sent to their respective left and right headphone outputs. The HRIR used is dependent on the direction that the sound source is coming from. It is important to note that this method only works using headphones and that these binaural simulation techniques do not work using stereo loudspeakers.

A major issue surrounding binaural simulation using HRIRs is that each sound source requires its own HRIR. For a large number of HRIRs, the computational cost of so many convolution operations can be great. Furthermore, moving sound sources require complicated interpolation between the different HRIRs. This is further complicated by the fact that humans implement head movements in order to fully determine the location of a sound source that falls within the cone of confusion. For this reason, the use of HRIRs to simulate binaural hearing is usually inappropriate for real-time situations. This is particularly true in the case of VR, where a sound source's location may be controlled using AI.

Ambisonic Systems

Ambisonic systems utilize a (usually) spherical array of loudspeakers that allow the user to position a sound source through a series of encoding and decoding algorithms that recreate the sound field. The audio file format used by ambisonics is called the B-format. It consists of two types: first-order B-format and the more recent higher-order B-format (Furness 2011).

First-order B-format contains four audio channels, designated the W, X, Y, and Z channels. B-format is designed to recreate the sound field using spherical harmonics. The mathematics that describes ambisonic systems is beyond the scope of this entry. For an overview, the reader is pointed to Fellgett (1973). Higher-order B-format adds more audio channels to the format, corresponding with higher-order spherical harmonics (Nettingsmeier and Dohrmann 2011).

Sounds may be captured for use in first-order B-format using a sound field microphone. This specialist microphone is actually four microphones combined: an omnidirectional microphone and three figure-of-eight microphones. The positioning of the figure-of-eight microphones corresponds to the X, Y, and Z axis and captures information on how the sound source is affecting the air pressure at the point of recording. The omnidirectional microphone is used as what is called the reference channel. These four audio channels are used to recreate the sound field in an ambisonic system.

Ambisonic panning is a two-stage process known as encoding and decoding. The encoding process is where a user may pan mono sounds. This is done by specifying the sound source position by specifying the location in terms of angles for the horizontal and vertical plane. The decoding process involves adjusting the decoding parameters to the speaker array currently in the room. This design choice means that the encoding of audio mixes remains unchanged, but can adapt to the speaker layout of the user.

Virtual Ambisonic Systems

Virtual ambisonic systems combine the two methods described in the previous section and were first described in Noisternig et al. (2003). It works by routing the output of the decoded ambisonic signals to HRIRs corresponding with the location of the speaker. This in effect creates

a virtual speaker. The outputs of these HRIRs are sent to the respective channels of the left and right headphone output, recreating the ambisonic system.

There are a number of advantages to this type of system. Firstly, virtual ambisonics limits the number of convolution operations to twice the number of virtual speakers being used in the decoding process. This means that it is particularly useful for a large number of sound sources. It is also useful for moving sound sources, as it avoids the need for any type of complex interpolation between HRIRs as the sound source moves location. This panning effect is also useful for implementing head motion tracking and shifting the location of the sound sources to correspond with the listener's head position via motion tracking.

Implementations

Ambisonics has recently become available for use in Unity VR through a plug-in from Google. For a tutorial on this topic, please see Ambisonic Audio (2017). Most implementations of virtual ambisonics have been restricted to academics researching the topic (Gorzel et al. 2011; Braun and Frank 2011; Kearney et al. 2012). However, in theory, it should be possible to implement it by routing the output of the ambisonic system to be convolved with the corresponding HRTFs. A library of HRTFs is available at Wierstorf et al. (2011) and Bernschütz (2013).

[2]Vincennes University, Vincennes, IN, USA

Synonyms

First-person shooter (FPS) game; Multiplayer game

Definitions

Multiplayer game = a game that is designed for multiplayer mode where two or more players are expected throughout the entire gameplay.

First-person shooter (FPS) game = a video game where a player takes on a first-person perspective when using gun and other weapons in combats.

Introduction

Overwatch is a 2016 team-based multiplayer first-person shooter (FPS) game developed and published by Blizzard Entertainment for PC, Xbox, PlayStation, and Nintendo Switch. Overwatch is set in a future where a conflict between robots and humanity necessitated the creation of a task force, conveniently called "Overwatch." In the game's primary competitive mode, players are arranged into two teams of six and compete on a variety of maps and game types. This allows the gamers to play in whatever way they believe is the best such as flanking or working together to push to the point on the map or allow for people to get in the backlines and take people off on both sides.

6v6 Team-Based Gameplay

Overwatch assigns players into two teams of six, with each player selecting from a large roster of characters, known as "heroes" with unique abilities (See Fig. 1). The teams use a variety of weapons such as guns, hammers, and turrets to secure point or move payloads to checkpoints. With Overwatch's 21 different maps to play on, it is always exciting to see where you end up fighting. Maps are split into four different play modes: assault, escort, hybrid, and control. Assault or "2CP" has a team trying to capture two objectives on a map within a set time. Escort is a mode in which teams are on either offense or defense. The offense team attempts to move the payload to objective points on a track within a timeframe whereas the team on defense attempts to stop the progress until time runs out. Hybrid is a combination of the two previous modes where the defense team attempts to stop the offense team from taking the objective and moving the payload further into the map. Control is a mode in which teams attempt to fight over a specific area of a map. This can be from the inside of a temple to the common area of a small town. Teams are equally spread out so that each can get to the point at the same time. There is also a variety of other game modes which range from low gravity – allowing characters to float in the air for a while, all the way to no limits – allowing all players to play the same characters if they wish, which is not the case in unranked or ranked modes. Ranked is a game mode where many people play to rise in the ranks ranging from bronze to grandmaster.

A Brief Beginner's Guide

With a steep learning curve, Overwatch is a game that is difficult to master. However, it is easy to get started in playing Overwatch:

Overwatch: Team-Based Multiplayer First-Person Shooter Game, Fig. 1 Hero gallery

1. Purchase hardware: Overwatch runs on a variety of platforms including PC, PlayStation, Xbox, and Nintendo Switch.
2. Install Overwatch: Overwatch 2 is free to download and play.
3. Create an account: After installation, a player will need to create an account on the Overwatch website. However, players who already have a Battle.net account can sign into Overwatch.
4. Choose your hero: In Overwatch, the player chooses a hero with unique abilities and strengths. The player can switch between heroes during the game to adapt to the dynamic situation.
5. Play a game: The player can choose from several game modes, including Quick Play, Competitive, and Arcade. Quick Play mode offers a casual setting for players to get familiar with the game. Competitive mode provides a ranking system in a more serious setting for players to compete against other players. Arcade mode are frequently changing game modes and rules.
6. Communicate with team members: Overwatch is a team-based game, and therefore communication is key. Players use voice chat or text chat to communicate and coordinate attacks.
7. Work together: Teamwork is essential in Overwatch. All team members must work together to capture objectives, defend key positions, and defeat the opponent team.
8. Practice makes perfect: Overwatch has a steep learning curve, and therefore it takes a lot of practice to become proficient at the game.

Reception

In the first week of release over seven million copies were sold worldwide, becoming one of the top selling games in May 2016. As more characters and maps were added to the game, more players joined and the game grew steadily over time. Special events such as Halloween brought Junkenstein's Revenge which is a mode where an endless wave of robots would swarm at a castles door that the players have to protect with a limited number of characters available and can be augmented with modes that can periodically change what character you are. Another event that many people look forward to each year is Christmas which offers more modes that are not normally available, with new skins and emotes that can only be obtained in the Christmas event. However, Blizzard has become complacent with the game, believing it had become perfectly balanced and did not need to be changed, leaving

players to make the game fun themselves. With the release of Overwatch 2 in October 2022, the sequel becomes a free-to-play game.

Esports

Overwatch has its own league of 20 teams that have played about 40 matches, each lasting anywhere from 45 min to 2 h long. (Almughrabi et al. 2022) Six teams with the best records of the year go on to the playoffs ending in the top teams splitting a winning prize pool of $1.5 million dollars. There is also the Challenger Cup which is one step below the overwatch league that competes for a few days to show off their skills for the possibilities of being signed by the leagues.

Conclusion

Overwatch has sold over 50 million copies (Radić 2021). With the launch of Overwatch 2, players have lost the ability to play the original version of the game (Holt 2022). Gamers are forced to play Overwatch 2 if they wish to play the game. But this can breathe new life into Overwatch by allowing more players to join due to the free-to-play business model. It was a rough start when Overwatch 2 was released to the public with long queue times and players being disconnected for seemingly no reason (Lowry 2022). With bug fixes and the promise of a constant release of cosmetics maps and new characters, Overwatch 2 remains one of best competitive team-based multiplayer first-person shooter game.

Synonyms

3D rendering; Engine architecture; Game engine; Scene graph engine

Definition

A game engine (Gregory 2018) is a software engine/framework mainly designed to develop video games while providing built-in libraries, tools, and/or components for game development-related functionalities such as model rendering, physics, levels, animations, networks, audio, and artificial intelligence (AI).

Three-dimensional (3D) rendering is the concluding stage of creating two-dimensional (2D) images from 3D models, followed by creating 3D models and adding material and light to the objects and the environment in a scene (Saito and Takahashi 1990).

A scene graph is a data structure representing the spatial and logical connections of the elements in a graphical scene via a collection of nodes (Fisher et al. 2011). It is commonly used in game engines and computer graphics libraries and software.

Introduction

Panda3D (Goslin and Mine 2004) is a free and open-source game engine under the revised Berkeley Software Distribution (BSD) license as of May 28, 2008, to develop video games, simulations, and visualizations using programming languages of Python and C++, initially developed by Walt Disney Company's Disney VR Studio and currently maintained by Carnegie Mellon University's Entertainment Technology Center. The default game development language of Panda3D is Python, and the C++ programming language is the alternative language, while the Panda3D engine is written in C++.

Panda3D aims for the users to grasp the main functionalities in a short time and targets users with diverse experiences, from novice to senior game developers, industry professionals, designers, and academic communities by providing different sets of resources and documentation such as Panda3D manuals and application

© Springer Nature Switzerland AG 2024

https://doi.org/10.1007/978-3-031-23161-2

programming interface (API) references available for both Python and C++ programming languages, focusing on game programming, debugging, and performance optimization – with additional resources such as video lectures and glossary.

Panda3D has an active community contributing to the development of Panda3D code on the project's GitHub repository, responding to questions from the users on the forum, and also supporting the project financially.

Main Features of Panda3D and Example Games

Panda3D was written in the C++ programming language and is cross-platform compatible. Panda3D source assets can be updated and modified using its command-line tools, allowing the content pipeline to be automated and scripted so that the users can create customized content in a short amount of time. Panda3D features bindings for a variety of third-party libraries, including the Bullet physics engine, the Assimp model loader, and sound libraries like OpenAL (cross-platform 3D audio) and FMOD (sound effects), allowing for the integration of external resources with a focus on the code's reusability. Panda3D users can create their own rendering and graphics pipelines, allowing them to create complex end-to-end production pipelines. Performance profiling is accomplished with the pstats profiling system, allowing the performance of the generated output to be examined so that additional optimizations can be further implemented. Finally, Panda3D enables quick prototyping and provides an easy-to-use and end-to-end pipeline for creating an initial prototype while giving an easy-to-learn foundation to the users (Panda3D 2023).

Panda3D has enabled the development of various commercial games. Toontown Online (Mine et al. 2003) was a massively multiplayer online role-playing game released in 2003 and shut down in 2013 and allowed users to create their game characters and engage in combat and non-combat activities. Pirates of the Caribbean Online (Pirates Online 2023) game was released in 2007 and discontinued in 2013, a multiplayer game based on the Pirates of the Caribbean franchise. A Vampyre Story (A Vampyre Story 2023) was another mainstream video game built using Panda3D and launched in 2008, where the game's story revolved around a vampire opera singer in Europe during the 1890s. Ghost Pirates of Vooju Island (Ghost Pirates of Vooju Island on Steam 2023), a visual adventure game, was another single-player commercial video game created utilizing Panda3D.

Conclusion and Discussion

Open-source and free-to-use game engines have revolutionized both the gaming industry and academia in terms of democratization of content generation while acting as catalysts and bridges toward diminishing the gaps within these two communities. Accessibility, availability, automation, and AI-based aspects of these advanced pieces of software and frameworks have benefited small game companies and academic research groups within universities in particular. Access to the resources, forums, and communities created around these engines has provided equal opportunities to hobbyists and commercial game firms, as well as a noteworthy boost to the rise in interest in game development and content creation. Higher education game development programs, theme-based game jams, advancements in hardware performance, and the emergence of virtual reality, augmented reality, and mixed reality headsets have massively transformed the game development domain. Furthermore, having long served as a testbed for AI tools, advancements in the game development software and hardware have made a huge impact on game AI, procedural content generation, and reinforcement learning – with recent human-level achievements in the game AI. Finally, current large language model-driven chatbots and tools have aided and enabled the creation of complex and sophisticated game content.

The road paved by the accessibility of game engines, where reaching resources, information, and hardware has enabled a fresh perspective full

of new possibilities, is predicted to lead to new and exciting journeys as well as advancements, creativity, and accessibility in game development.

Parasocial Phenomena in Video Games

Gabriel Elvery
University of Glasgow, Glasgow, Scotland

Synonyms

Paracommunication; Parasocial interaction; Parasocial relationships; PSI; PSP; PSR

Definition

The term parasocial is used to refer to interactions by consumers with a media persona via

This publication was supported by the University of Glasgow's Lord Kelvin/Adam Smith (LKAS) PhD Scholarship

technology. The term was originally used as a descriptor of one-sided interactions with television or radio personalities designed to create intimacy. However, further research on these phenomena have begun to broaden the definition in response to the digital age. Researchers have begun to investigate the term's applicability to interactions which include simulated reciprocity, such as in video games by nonplayer characters (NPCs), and social interaction mediated via technology that blurs the line between parasocial and social interaction. Furthermore, the term "parasocial" is no longer confined in its use to the creation of intimacy, and theories of parasociality are beginning to be applied to other kinds of mediated relationships, which are as varied as social interaction.

The Origin of the Theory of Parasocial Interaction

What we today refer to as parasocial phenomena began as the theory of parasocial interaction (PSI). The term "parasocial interaction" was coined by sociologists Horton and Richard Wohl (1956) in their paper subtitled "Observations on Intimacy at a Distance." Horton and Richard Wohl (1956) defined parasocial interaction as one-sided social engagement mediated via a mass media figure (such as a television personality) that elicits a feeling of intimacy from the viewer akin to the experience of a "face-to-face relationship between spectator and performer." This engagement is different from exchanges with friends or acquaintances as it can only be "one-sided" (Horton and Richard Wohl 1956). Though one-sided, parasocial interaction is similar to more traditional social interaction in how it is formed and maintained; the interviewer may judge the on-screen actor by first impression and "through direct observation and interpretation of [their] appearance," which breeds familiarity with the figure over time, leading to the building of a "history" through "accumulation of shared past experiences" (Horton and Richard Wohl 1956). This first study identified techniques used in personality programs, such as talk shows, designed to make viewers feel a sense of intimacy with their hosts. Such techniques include having hosts mimic the "conversational style, and milieu of an informal face-to-face gathering," which gives "the impression that he is responding to and sustaining the contributions of an invisible interlocutor" (Horton and Richard Wohl 1956). Hosts may also play a part in intentionally blurring the line between observer and performer by sitting with a studio audience or taking calls from viewers at home (Horton and Richard Wohl 1956). Rosengren and Windahl (1972), drawing inspiration from Horton and Wohl, created a "typology of relations" split into four kinds of relationship with two overlapping categories, "interaction" and "identification" (p 173), which was further modified in 1976 by Rosengren, Windahl, Hakansson, and Johnsson-Smaragdi. The most commonly used scale was developed by Rubin, Perse, and Powell (1985) whose 10-item version is the most widely applied. Further development on such scales continues, as detailed in Auter and Palmgreen's (2000) work, in which a summary of prior scales can be found.

Parasocial Phenomena

The lack of consensus surrounding the definition and measurement of PSI has resulted in conceptual confusion regarding its definition. This has led to a plethora of attempts to clarify the concepts and consider how they may be used more consistently. Liebers and Schramm (2019) coined the term "parasocial phenomena" (PSP), which is useful shorthand for describing a broad spectrum of PSI as it encompasses all types of parasocial activity including "parasocial interactions, parasocial relationships, parasocial breakups, and so on." The most important distinction they draw is between parasocial interaction and parasocial relationships (PSRs). Liebers and Schramm (2019) use the term parasocial interaction to define interactions with a media figure that occur during media consumption, and parasocial relationships to describe parasocial phenomena that move beyond the confines of media consumption and "encompasses cross situational relationships

between the audience and media characters." Considering this definition, one may see parasocial interactions as fleeting encounters which, over time, make up the parasocial relationship a lasting affective impression left upon the viewer and carried with them in the media figure's absence.

Parasocial Phenomena and Identification

David C. Giles (2002) also completed a detailed review of the topic and proposes conceptual clarifications for use in further research. Giles (2002) untangles the amalgamation of parasocial phenomena with other psychological theories: most prominently identification. Giles (2002) draws on the work of Cohen (1999), Rubin (1981), Rosengren and Windahl (1972), and Feilitzen and Linné (1975) to consider the ways PSI is different from identification, which may play a part in PSI, but is a separate principle (Giles 2002). PSI can involve identification, which can be described as "the sharing of perspective," but users "may still engage in PSI without sharing perspective" (Giles 2002) – the two are different processes, though not mutually exclusive.

Categories of Parasocial Phenomena

Giles (2002) also makes an important distinction regarding the types of figures which facilitate PSI and PSR by creating three categories used to differentiate between them. The category of "first-order PSI" is comprised of media figures such as talk show hosts that project an authentic persona and "[address] the user directly"; "second-order PSI" is inhabited by representations of fictional characters played by actors, and "third-order PSI" consists of "fantasy or cartoon figures who have no real-life counterpart" (Giles 2002). Giles (2002) situates these categories on a continuum ranging from social to parasocial: a "one-on-one meeting with a media figure" that has real life social implications is at one end of the spectrum, while at the other is third-order PSI in which a real-life encounter or relationship with the figure is "impossible" as they are entirely fictional.

Applications in Game Studies

There have been few video-game-specific studies relating to PSI, and researchers who use PSI tend to lapse into similar patterns of amalgamation and conceptual confusion to those described above. Nass and Moon (2000) conducted a study which observed how users "mindlessly apply social rules and expectations to computers" in a paper which seems to explore a kind of PSI, without terming it as such, and Klimmt et al. (2009) mention PSI with regard to video games but focus on identification. Studies which consider PSI in relation to players' avatars are by far the most common in Game Studies: Chung et al. (2007) investigated the "influence of avatar creation on attitude towards avatar, empathy, presence, and parasocial interaction of female non-game users"; Banks and Bowman (2016) examined the relationship of the player to their avatar based on "along a continuum of non-social to parasocial to fully social," integrating a parasocial approach they term "character attachment" with a social approach they describe as "player-avatar relationships [PAR]"; and Jin and Park (2009) conducted a study examining the relationship between players' feeling of "self-presence" in a video game as mediated via their avatar, using PSI as a loose means of describing "players' interpersonal involvement with their avatar."

There are two particularly notable contributions to PSI discourse which both further develop the concept and contribute meaningfully to the use of PSI in Game Studies research: from Tilo Hartmann (2008) and Katrine Kavli (2012). Hartmann's (2008) paper acknowledges that digital media has the capability of facilitating more complex PSI than the mass media figures Horton and Richard Wohl (1956) describe and resituates the theory for the study of new media in general. Meanwhile, Kavli considers parasocial phenomena with a tighter focus on PSI with digital entities.

Paracommunication and Mediated Communication

Hartmann (2008) proposes key amendments to the schema, primarily based on the differing level of reciprocity that video games can offer, which old media cannot, observing that the original theory "only focused on processes of character perception" and should be called "parasocial processing of media characters" to take into account the unilateral direction and simple nature of engagement with mass media figures. On the other hand, mediated interaction via interactive technology, such as video games, offers a different form of PSI which more closely resembles communication as they "build on mutual awareness and include symbolic behaviour" (Hartmann 2008). Hartmann (2008) calls this more reciprocal exchange, "paracommunication," broadening the definition to include "most types of mediated interpersonal communication," arguing that communication with real people via technological means is likely to have a parasocial element due to the nature of the platform. Hartmann (2008) argues that for parasocial communication to occur, new media figures should be both "sufficiently authentic and distant." Distance, here, refers to the "perceived social distance" between the user and the person, or character, they are interacting with and is best summarized as "the degree of conviction the user has that his or her behavioral expressions do or do not have an impact on the symbolic behaviour of the other." Hartmann (2008) proposes that users are more likely to engage in playful parasocial communications with entities if, based on their "individual interpretation of the social situation," they perceive the consequences as being minimal – the greater the perceived social distance, the greater the freedom of interaction. Hartmann (2008) gives multiple examples to illustrate this point, arguing that video chat facilitates a level of paracommunication as some of the consequences of conversation are removed via the physical distance between participants. Similarly, virtual worlds such as Second Life (Linden Lab 2003) allow a degree of anonymity which may further reduce the perceived consequences of a user's actions (Hartmann 2008); therefore, paracommunication with an NPC, in most games, would rate as being playful – playful here meaning that there is a perceived lack, or low risk of, of real-life consequences.

Paracommunication and "Authenticity"

As well as being sufficiently distant, Hartmann (2008), like Giles (2002), argues that to encourage PSI, media figures should seem authentic. Hartmann's (2008) definition of realistic more thoroughly acknowledges the nuances of character design than Giles' (2002) more narrow definition. Hartmann (2008) suggests that "a character's behavior seems to be more important than its outer appearance"; authenticity is dependent on whether users "attribute a general intelligence and self-determination (i.e., an "intentional stance") to a character." The quality of being realistic, then, can be defined in terms which are less about the mimetic appearance of a character, and more about whether the character is "real" enough in emotional terms and capable of mediating affective engagement. Even if the media figures are distant and authentic enough to facilitate paracommunication, this may only occur if the user is receptive to it. Hartmann (2008) argues that users must be situated in "an involved mode" rather than an "analytical mode." "An involved mode" refers to narrative and affective receptivity, whereas an "analytical mode" creates an affective distance. In an involved mode, users, "at least momentarily—tend to believe in what they perceive."

Parasocial Phenomena and Video Games

Where Hartmann (2008) considers the application of PSI to technologically mediated communication in general, Kavli (2012) focuses specifically on how PSI "can be directly translated into the field of digital games" by analyzing different definitions of the term and considering its deployment in the field of Game Studies thus far. Kavli (2012) outlines the different digital entities which

may facilitate types of PSI: "bots" (NPCs), the "player avatar or character," and "other players' representations" (in a multiplayer game, for example). Kavli (2012) considers each of these digital entities using Horton and Wohl's (1956) original criteria. Unlike Hartmann (2008) who describes exchanges between players and NPCs as reciprocal, and categorizes them as paracommunication, Kavli (2012) observes that these interactions still have much in common with the mass media figures of Horton and Wohl's (1956) theory and notes that although players "may get the impression that the conversation involves [them] and the digital persona, the persona can only follow the static dialogue tree defined by a programmer." This, however, does not reduce the quality of the PSR for Kavli (2012) who notes that "some game characters succeed in establishing a relationship with a player that is so deep and heartfelt that the player wishes to break the boundaries between the digital and physical world in order to pursue the relationship" citing an article (Lah 2009) which documents the marriage of a man to a video game character.

Simulated Sociality

Kavli's further elucidation of PSI with NPCs need not negate Hartmann's (2008) work but clarifies it: If characters are authentic as Hartmann (2008) and Giles (2002) suggest, the reciprocity of the interactions need not be genuine but must have the appearance of being realistic. Game characters who offer third-order PSI may further blur the line between parasocial and social interaction, as the fictional nature of the characters denies players any possibility of meeting them, but may simulate a greater degree of reciprocity than PSI with a film or television character. When a viewer watches a personality program, their existence is generic and scripted interactions cannot change, whereas when they play a game, their icon and its programmed properties exist to the NPC, meaning that the NPC can address the icon directly and respond to them depending on the functionality of the software. At a basic level, NPCs will speak back when the player chooses to interact with them, and at a more complex level their responses may change depending on the player's selection of dialogue or relationship parameters. In a television show, hosts will continue speaking whether the viewer is there or not, decreasing the perceived authenticity of the interaction.

The Implications of Parasocial Phenomena

Throughout the reviewed literature, it is broadly agreed that PSI and PSR can serve as an extension of, and supplement for, healthy social interaction. Giles' (2002) model "presents PSI as an extension of normal social activity by considering shared and different qualities of social and parasocial encounters." Jarzyna (2020) has proposed that technology such as Netflix and social media paired with the COVID-19 pandemic has resulted in PSI serving as "social surrogacy" in which PSI is being used as a means to decrease the deficit in social needs and supplement real relationships by "filling social needs and decreasing loneliness," and Cohen (2014) states that relationships with fictional characters are "meaningful to us and in that sense they are very real." There is also research which suggests that "through parasocial relationships, people with low self-esteem can gain some of the benefits of real relationships without the fear of rejection" (Derrick et al. 2008). Although the reviewed literature (note Giles 2002; Kavli 2012 and Lah 2009) has identified risks of pathological behavior in which parasocial phenomena become detrimental to users' social lives – for example, when participants fail to identify when a relationship is parasocial and "believe that their PSI has been reciprocated by the media figure" (Giles 2002) – these cases are outliers and often connected to media figures who are real people. Such research findings across disciplines have provided a solid foundation from which to further explore parasocial phenomena, and such research could provide insight regarding the effects of utilizing technology to supplement social interaction, as well as exploring what such interactions can tell us about off-screen social dynamics.

PBL-Based Industry-Academia Game Development Education

Yukiko Sato
Cygames, Inc, Shibuya, Tokyo, Japan

Synonyms

Constructionism; Constructivism; Inductive Learning; Situated Learning

Definitions

PBL (Project Based Learning)-based Industry-Academia Game Development Education is a pedagogical method for teaching essential theories, technical, and interpersonal skills of game development, by uniting the learner, game industry staff, and faculty from academia. The learners set a project, aiming to create an artifact to solve real-life problems, while the instructors in academia and industry both support the learners' progress. Throughout PBL, two institutes exchange knowledge, through lecturers, by providing the required tools and venue for game development, giving feedback, as well as by evaluating the completed projects to foster the future game developers.

Introduction

Following the rapid growth of video games and the widespread success of the gaming industry (Newzoo 2019) games research is becoming more diverse as academic communities and universities are responding to this change (Kultima 2015). Research publications, seminars, conferences, and associations on game related studies have been expanding on an international level (Mäyrä 2008). To this extent, some universities attempted to expand, share, and exchange teaching methods for game design inter-culturally (Engström et al. 2020; Pirker et al. 2016; Ruch 2019). Current academic game institutes offer courses aimed to prepare students for entering the creative, multimodal, interdisciplinary gaming industry, which requires not only knowledge of the technological aspects for game production but also competency for collaborative teamwork (Sillaots and Fiadotau 2018). Before this background, the importance of industry-academia collaboration is emphasized in terms of enhancing research and education for future game development (Godin et al. 2020), where students can earn practical training required in the industrial context (Mikami et al. 2010) and can share latest tools, technologies, and art techniques for current and future teaching and research (Kenwright 2016). Through such collaboration, the industry has a chance to headhunt good students (Bidarra et al. 2008). However, the difficulties of promoting such activities remain. Previous research has shown the difficulties in bridging these two institutions. For instance, problems of different priorities exists (Ficocelli 2007), and furthermore industries tend to be hard to reach for academic staffs (Parberry et al. 2005; Mikami et al. 2010). This results in a wide gap between industry and academia. As the industry tends to grow dramatically, it is challenging for academia to keep up and to reflecting the constantly changing cutting-edge requirements of the industry (Ritzhaupt 2009), which is gradually creating an expectation gap regarding the students' required skills to work in the industry (McGill 2009). However, the unique working environment in the industry is difficult to replicate in academia and the commonly used traditional approaches in university curricula fall short to meet the industry's demand (Hogue 2011). In order to overcome this problem, some companies are gradually opening their doors to collaborate with academia and have been successfully supporting game design and technology education through PBL (project-based learning) game development courses and projects. This

entry introduces how academia and industry can work together by integrating such PBL-based learning activities in their teaching methods. The PBL between industry and academia is constructed through considering multifaceted levels and this entry shows the essential 12 dimensions, which is meant to guide and assist in the decision-making process and to further discuss the possibilities of industry-academia collaboration for video games development and education.

Project Based Learning (PBL)

Project based learning is a student-centric and inductive pedagogical approach, in which the learning occurs as the students work on a project to tackle a real-life problem through investigation, discussion, and collaboration with others. This approach reflects the theory of constructionism, as the learners benefit from social interactions and sharing throughout the process of creating an artifact (Papert and Harel 1991) as well as situated learning (Wertsch 1985), which states the learning in context of practice in the learning process, internalizing knowledge through activities supported by mentoring. The base of this approach goes back to the beginning of the twentieth century, as John Dewey introduced such hands-on learning methods through *Learning by Doing* (Dewey 1986). There are essential components of projects practiced in the PBL, (1) the project requires an open-ended question or a problem created by the learners themselves or teachers (however, they shouldn't be constrained) and (2) the activities result in the form of artifacts, such as products, presentations, or any kind of presentable form at the end (Blumenfeld et al. 1991). In contrast to the traditional top-down deductive teaching method, the instructor takes the role as a facilitator during the PBL, providing resources, guidance, and instruction (Barrows and Tamblyn 1980), as well as feedback (Larmer and Mergendoller 2010). PBL is effective when it involves active learning, is goal-orientated, practice-based, contextualized, and interactive between teaching and/learning, as well as when it maintains the students' motivation and the impact of PBL affects students personal growth and achievements, including critical thinking, problem solving, communication, self-management, project management, and collaboration skills, which is transferable in today's rapidly changing and complex reality (Buck Institute for Education 2019). For game development and education, PBL approaches have gained attention in the field of computer science. Researchers/instructors attempted to integrate a PBL activity in traditional curricula, as students can thereby learn practical skills in the context of a real-life working situation and also earn life-long skills at the same time (Pirker et al. 2016). To this extent, creating games has been a popular method to realize PBL-based education, as the practice and process of game creation itself has been acknowledged as an efficient way to learn and practice multidisciplinary skills through collaborative learning (teamwork and communication) (Agterbos et al. 2019). Creating games awake students' learning motivation by enhancing autonomous learning in nature (Wu and Wang 2012). Instructors related to the field of game development have blended PBL-based project activities into their teaching. For example, PBL activities in academia have been combined with classroom lectures as an essential capstone in their courses (Zagal and Sharp 2011). Long-term PBL-based game development projects, longer than one semester, are introduced in some universities in a form of a thesis or graduation project to earn a degree in the field of game development (Mikami et al. 2010; Kenwright 2016). To realize the PBL blended with real-life experiences of the industry, game developers, technical staffs, executives, and industry researchers have been cooperating with academia. Referring to previous research, the following section introduces how academia and industry can construct a PBL-based education together by considering twelve essential dimensions.

12 Dimensions of Industry-Academia PBL

Categorizing previous works and courses on game development for higher education involves

PBL-based learning with collaboration of industry and academia. The following 12 major dimensions and their subsequent elements are essential components to determine a collaborative course on creating games (See Table 1):

Environment

Where students are taught about game related knowledge, where students work on game creation as group work, as well as where student-instructor interaction occurs differs depending on the physical setting of the learning/working environment. Most PBL activities are organized along with traditional classroom-based lectures in university. Some projects are carried out in a hybrid form: integrating both spaces of university and the industry, as the students conduct on-site team work in the company and development activities at faculty labs (Zajc and Starcic 2017). In other cases, online communication methods are integrated. For example, a Japanese mobile game company, Cygames, Inc. and the University of Skvde combined cyber and physical spaces to educate students from Japan and Europe, as students work on-site with asynchronous support from academia, as directors in the industry and academia supported the students' activity together (Sato et al. 2020). Ubisoft (2019) established a complete online-based game development training program with Concordia University, allowing the universities to adapt their program in courses by collaborating with the company.

Scale

The scale of the learning environment differs in terms of the geographical level of collaboration. Institutions tend to collaborate locally, which universities and companies in the same region partner to educate students. For example, Dutch game developers and Microsoft Netherlands supported the game development activities at the Delft University of Technology (Bidarra et al. 2008), EA and game developers in British Columbia partnered with the University of Victoria in USA (Estey et al. 2010), Disney, Sony, Nvidia, and AMD collaborated with University of Edinburg in Scotland (Kenwright 2016). Cygames, Inc. in Japan and University of Skvde in Sweden collaborated to support the game development projects of Swedish students in a rare cross-cultural collaboration (Sato et al. 2020).

Faculty Combination

As game development requires interdisciplinary developers, researchers introduced cross-disciplinary PBL activities to work on the project. The combination of faculties range from working on a project in a single faculty to collaborating with multiple faculties or universities, as students are required to form teams and assign roles by themselves to develop games in a real-world context (Shoop et al. 2019).

Modality

Types of industry-academia collaboration differ depending on when and how long the game development program last. The shortest is set to a 4-week project as the students went through the iterative cycle of game development, the longest is a 4-year game development course in which the students pursue a degree related to game development and technology (Mikami et al. 2010; Kenwright 2016). The most common type of the PBL-based projects are conducted per semester for 13–14 weeks, as instructors give lectures and students work on projects during as well as at the end of the semester as n assignment for final evaluation. PBL education can also take the form of an internship for approximately two months, as the students work on their projects collaborating with industry staffs (Sato et al. 2020).

Target Level

PBL-based learning is adaptable for a wide range of levels of students, from beginner courses teaching the fundamentals of game development to advanced contents, such as collaborating with the company to work on gaming technology. However as Yun et al. (2016) state, participating students should be on the same level to avoid elementary problems preventing the team work among students.

PBL-Based Industry-Academia Game Development Education, Table 1 12 Dimensions of industry-academia PBL-based game development education

Category	Type	Explanation
Environment	Academic institution	All activities are conducted at an academic institution
	Hybrid	Activities take place both in academic institution and the industry site
	Cyber-Physical	Learning environment integrates cyber space for communication and physical space for hands-on activities
	Online	Students learn game development know-how through online-based education
Scale	Local	The education is conducted in a particular single region with participants in a monolingual environment
	Global	The education is conducted in a global setting with participants from different regions in a multilingual situation
Faculty combination	Single	Project is conducted with members of one single faculty
	Internal collaboration	Students from different faculties studying in the same institute participate in the course to learn game development
	External collaboration	Two or more academic institutes studying different disciplines collaborate with each other
Modality	Project	PBL projects are conducted within a month
	Internship	A mid-term project conducted for 2–3 months
	Courses	Academic courses for game development range from short (13–16 weeks), middle (1–2 years) to long terms (4 years)
Target level	Beginner	PBL is targeted to teach a group of freshmen or sophomores (first to second year students).
	Intermediate	The group includes juniors and seniors
	Advanced	Projects are conducted by senior students mixed with graduate school students
Pedagogical focus	Game design and research	The course is focused on teaching the holistic process of game creation and production mostly centered in the field of Computer Science
	Game tech. and research	Courses are tailored to learn gaming technologies as well as engineering
Learning approach	Top-down	This approach examines completed games and reverse engineers to work on the individual elements
	Bottom-up	This approach first examines the concepts and game components separately and then begin to construct games and tools
Goal	Multidisciplinary	The course is aimed to experience, learn or collaborating with the diverse required skills in game development
	Soft-skills	These include necessary skills for team working to complete a game, such as collaboration, communication, and plan management
	Technology	The course is aimed to research specific techniques for game development, such as programming and other artwork
	Iteration/Agile	Students are expected to learn the iterated cycle of game development beginning from planning, prototyping and user tests
	Meaningful design	The aim is to develop a game for real-life use by applying user centered design techniques
Assessment	Summative	The final outcomes of the students' activity are evaluated to measure their learning
	Formative	Instructors and learners evaluate the progress of assignments or projects and give feedback towards the completion of the project
Role of industry	Instructor	Industry staff contributes to education as lecturer, mentor, mission provider for PBL or project evaluator for final assessments
	Environment provider	Industry shares their working office environment and offer equipment support to students

(continued)

PBL-Based Industry-Academia Game Development Education, Table 1 (continued)

Category	Type	Explanation
	Project collaborator	Academia and industry work together through collaborative research projects, sometimes involving students' thesis activities
	Program co-funder	Industry works with academia to establish an educational course to foster students
Communication method	Physical	Industry and academia communicate in a physical space, such as office meetings or lectures and contests provided at universities
	Cyber	Instructors from industry and academia as well as students communicate with each other through an online communication platform
Feedback	Student-Student	Peer review and feedback are given between students
	Student-Instructor	Instructors in academia and/or industry review students' progress through reports or meetings and give feedback to students' individual or group work

Pedagogical Focus

There are diverse aspects of what the teachers aim to teach through PBL. This can be largely categorized into two major categories: game design and research, or game technique and research. The former involves a focus on teaching from artworks in game development (Parberry et al. 2005), critically analyzing game elements (Whitehead 2008), learning the SCRUM/agile development cycle through pitching, prototype development and user testing (Bidarra et al. 2008; Shoop et al. 2019; Schoenau-Fog et al. 2019), experiencing or preparing for the real-life working environment in the gaming industry (Zajc and Starcic 2017; Estey et al. 2010), potentially in a cross-cultural context (Sato et al. 2020), as well as acquiring competitive behavior and entrepreneurship (Yun et al. 2016; Hogue et al. 2011). The latter focuses on teaching the technical aspects of creating games, such as obtaining specific professional skills required to be a programmer, 3D artists, technical artist or sound artist, and management skills involving engineering (Mikami et al. 2015).

Learning Approach for Game Development

Lecturers' approaches towards PBL-based game creation and learning can be divided into (1) top-down and (2) bottom-up approaches. In the top-down model, students examine completed games and reverse engineers them and understand the details of what composes a game. (2) The bottom-up approach requires students the practice of research, critical analysis, brainstorming, and improvisation techniques to as they are thought how to create a game (Kenwright 2016). In top-down approaches, some lectures are gamified, as the students learn game design and its structure by completing missions in an originally developed game (Ubisoft 2019; Parberry et al. 2005) and complete a game creation project at the end. The bottom-up approach involves learning through problem solving in the form of iterative collaborative group works, by following the form of game production, which is to conceptualize, develop, and playtest a game (Schoenau-Fog et al. 2019). Regardless of the major approaches, unique styles of teaching are combined with the development activity, such as game competitions (Yun et al. 2016; Parberry et al. 2005; Whitehead 2008) as well as peer evaluation (Estey et al. 2010) and presentation at game shows (Mikami et al. 2010). Hogue et al. (2011) conducted a workshop, in which students worked on holistic game production by developing games, user testing, business plan, marketing plan, and pitch presentations including the creation of a game trailer, for which the industry members took part in the evaluation. In terms of lecturer support, one-on-one frequent support from lecturers and mentors are noted throughout some projects, as the members from industry and academia both plays a role to guide the students to complete their game (Sato et al. 2020; Shoop et al. 2019; Zajc and Starcic 2017).

Goal

PBL-based game development courses have multiple goals of the following by learning the theory and practice of game development: (1) inter-/multidisciplinary skills, as game creation requires group work across different disciplines (Yun et al. 2016); (2) industry-relevant competency, which is not only aimed at the students achieving technical know-how of game development but also soft-skills, such as collaboration, critical-thinking, communication, management skills, and to give and receive critiques from others, as well as adapting to existing codes in the industry (Estey et al. 2010) and research and development skills (Mikami et al. 2010); (3) Agile/SCRUM and iteration, related also to industry competence, this process of software development is set as a pedagogical goal, as it aims to provide the students with contextual knowledge and exposes them to the importance of iterative learning loops, such as failure and reflection (Shoop et al. 2019); (4) User oriented development, as this step is common in the practice of the game development cycle, students go through the iteration of user testing and development, aiming to create a meaningful game for real-life use (Schoenau-Fog et al. 2019); (5) Entrepreneurship, game development courses in schools oriented to foster entrepreneurship also aim to teach students the skills of business and entrepreneurship in the games industry, teaching them skills of beginning a start-up company (Yun et al. 2016).

Student Assessment

The performance of students is assessed through summative or formative assessment methods or a combination thereof. Most projects take the summative assessment approach as the lecturers grade the final product: the artifacts, such as games and presentations, are created and submitted at the end of the course for evaluation. The formative assessment focuses on the students progress, through daily reflections of the learners or peer-to-peer review activities. The online course by Ubisoft (2019) provides several online learner analytic tools to keep track of students' performance. On the other hand, instructors can analyze texts produced by students and instructors in the form of self-review reports and feedback by utilizing natural language processing (Sato et al. 2020), to see how the students' activity and behavior changed throughout the PBL-based practice.

Role of Industry

As there are several combinations of pedagogical foci, approaches, and goals, the way of how the industry can be involved in the academic projects share similar models among different PBL-based educations: (1) The role as an instructor: the most frequent role of the industry is to provide students with the motivation and vision to work in real-life as lecturers (Yun et al. 2016; Parberry et al. 2005) and mentors/guide (Sato et al. 2020; Shoop et al. 2019; Zajc and Starcic 2017) for game development projects. Industry members are also invited to evaluate the outcomes of the students as Hogue et al. (2011) affirm that developers evaluating the final projects ensure higher quality and motivation as well as an opportunity to provide further feedback to the students. It also becomes an opportunity for the industry to acknowledge the skills of students (Schoenau-Fog et al. 2019; Bidarra et al. 2008). (2) The role as a provider: The industry opens their office to welcome students for internships (Sato et al. 2020) or as project work space (Zajc and Starcic 2017) as the students can experience the development in context of a real-life working environment. However, this requires careful planning between academia and industry as there is a difficulty of reflecting the student's work in the industry to the students' academic assignment (Sato et al. 2020). (3) Industry can work with the academia through professional collaborative research, where students work on research projects with the industry. In such collaborations, the industry offers support such as access to tools (hardware and software) and technological equipment. In such cases, the industry is involved as a co-founder of the game development courses at academia and further involved as a steering committee to design the game development course in academia (Mikami et al. 2010; Kenwright 2016), which enables the faculty to access information of new technology, insights, and trends of the rapid game industry.

Communication Method

The communication between industry, academia, and students takes place either online by utilizing communication platforms or in physical spaces. Cases of the three groups sharing a mutual communication space are seldom. Students and faculty can contact the industry through final presentations at the university, or in contrary, the students only have direct contact to the industry as they earn feedback. In terms of global communication and game development, the three groups can establish a TRIAD education model utilizing an online communication space, enabling a transparent and asynchronous communication to guide the students throughout their PBL project between industry-academia in a cross-cultural environment (Sato et al. 2020).

Feedback Source

Feedback in PBL is provided by faculty, industry, and students (peers). Emphasizing the efficiency of feedback in order to completing a game in a semester course, Yun et al. (2016) mention the effect of weekly mentoring to guide the students so that they will not be overambitious about their game development, consulting the students by determining what game components should be prioritized and designating milestones. Estey et al. (2010) emphasizes intensive peer-review activities, as the students assess written reviews on playtests and pitches, as the author claims that this helps the students getting acquainted with evaluation activities in the industry. The industry also provides feedback to the students' project, which not only helps the learners improve their skills on game development techniques but also learn how to review game design ideas by transferring techniques of plus/deltas, fast track postmortems, and sprint planning (Shoop et al. 2019) as well as to collaborate and communicate with the staffs from different positions and cultural backgrounds (Sato et al. 2020).

Multiplayer Online Game, MOG; Distributed Virtual Environment, DVE; Massively Multi-player Online Games, MMOG; Peer-to-Peer, P2P; Area of Interest, AOI

Definition

The term "peer-to-peer gaming" refers to all those mechanisms and techniques aimed at supporting a multiplayer, synchronous, and interactive networked game by using the computational resources of the players themselves.

Peer-to-Peer Gaming

Computer gaming greatly profited from the worldwide availability of the Internet in the mid-1990s and the consequent popularization of multiplayer online games (MOGs). A very popular genre of MOGs are massively multiplayer online games (MMOGs), which are large-scale applications supporting a large amount of players worldwide concurrently sharing a real-time virtual environment. MMOGs are naturally organized as a centralized client/server architecture: a main server maintains and shares the synchronized state of the game, whereas client players connect to the server to interact with the virtual environment and with each other. This imposes most of the load on the centralized server that, in a fraction of a second, has to receive requests from players, resolve conflicts to maintain consistency, update the game state, and send back the updated state to players. Furthermore, servers need to be maintained and operated according to the maximum peak load and have constraints of computational power, and network traffic concentrates in data centers.

For these reasons, decentralized alternatives to the centralized/server architectures (Ricci and Carlini 2012) raised a lot of interest among research and industry communities. Decentralized architectures are supported by a network of computational resources geographically distributed, rather than a large centralized server. A common characteristic of many decentralized proposals in the field is the application of peer-to-peer (P2P) principles and technologies for the management of the operations of the gaming platform. The main idea is to exploit computing and network resources of players to alleviate the load on centralized servers.

Nodes are connected to each other by one or more *P2P overlays* decentralizing and distributing core server operations, including the management of the game state and the multicast of messages. In principle, P2P-based gaming gives concrete advantages with respect to centralized approaches (Yahyavi and Kemme 2013). It requires a minimal fixed infrastructure to be operated. It is inherently scalable, as the available resources increase with the number of players. Moreover, these properties come with marginal or no costs for the game operator.

The use of P2P in gaming applications presents several differences with respect to other popular P2P applications, such as file-sharing. One notable difference is related to the content search. In a game, the interest of a player is often localized to only a certain set of events, whereas in file-sharing the desired content may possibly reside on any node of the network. Also, especially in multiplayer games, latency should be minimized in order to maximize interactivity, while it is no important in file-sharing applications.

Challenges

The application of P2P techniques naturally makes game architectures more complex and stems a number of challenges.

Due to their intrinsic distributed nature, every P2P game employs a certain level of replication of the virtual word state among peer resources. Replication is required essentially for two reasons. First it is mandatory for the definition of virtual environment: each participant must have its own copy of the state. Second, it is necessary to guarantee robustness and availability such that if a peer responsible for a piece of the state fails, another can take its place. If not properly addressed, inconsistencies lead to divergence on the game state, which in turn results in three major drawbacks (Delaney et al. 2006; Mauve 2000): (i) *divergence*, user experiences visual artifacts, (ii) *causality violation*, the actions are executed in wrong order, (iii) *expectation violation*, the user interacts with an inconsistent world. Further, especially in competitive games, inconsistencies can favor a participant with respect to the other, resulting in an unfair environment. In practice, when relying on best effort network, such as the Internet, strong consistency is hard to maintain due to the unpredictable latency and jitters. Therefore, client-side predictions are normally employed to avoid strong consistency in favor of an eventually consistent model. For example, local-lag and timewarp are *pessimistic* approaches that (Mauve et al. 2004) force an equal update delay to all replicas that reduce the inconsistencies. Conversely, Dead Reckoning (Pantel and Wolf 2002) is an *optimistic* approach in which each replica estimates the position of objects for a time interval, before finally synchronize with the other replicas. Another aspect that affects consistency regards the inherent unreliability of peer resources, i.e., they can leave the network voluntarily or abruptly, which might happen with short or without notice. This requires the DVEs to employ additional mechanisms for repairing the network and back up the game state.

Additionally, players' resources can be very heterogeneous in terms of computation capabilities, network, storage, and geographical positions. This heterogeneity has to be managed in order to exploit the right resource and avoid overloading. In fact, players interacting with each other and the surrounding virtual environment impose much load on the communication infrastructure, which can grow quadratically with the number of players (Nae et al. 2008). Further, load is intrinsically unbalanced as certain areas of the virtual world (i.e., hotspots) generate more load than the others. An overloaded peer resource managing a part of the world might deliver the events to the players with considerable delay, in fact compromising players' experience.

Finally, interest management refers to all those activities that are aimed to resolve a core but yet complicated problem in P2P games: for each player, to find the minimal subset of game entities (i.e., its *area of interest* (AOI)), that needs to be kept up-to-date. To find a proper AOI it is necessary to provide a smooth gaming experience and minimize resources utilization. An AOI too large can require more resources (especially network) than those available, while an AOI too small can fail to provide a good sense of interaction; either way it results in a degraded playing experience. It is worth noticing that interest management is a challenge also in centralized approaches, but it is exacerbated in decentralized contexts due to the partial knowledge of a peer node of the whole system.

Research in P2P Gaming

Research efforts toward P2P gaming are generally categorized into two broad families according on how they organized the overlay network that connects the players: *structured* and *unstructured*. In structured P2P DVEs (Bharambe et al. 2008; Kavalionak et al. 2015; Knutsson et al. 2004; Varvello et al. 2009), the overlay is defined according to a deterministic protocol that guarantees specific properties on the routing length and content-search performances. Popular structured overlays are Distributed Hash Tables (DHTs) such as Chord (Stoica et al. 2001) and Pastry (Rowstron and Druschel 2001). As far as concerns

interest management, DHTs guarantee $O(\log n)$ (with n being the number of nodes in the DHT) hoping to find any object in the virtual world but at the price of relatively high maintenance costs and limited adaptability of the overlay. Regarding consistency management, DHTs usually employ efficient and robust self-repairing mechanisms to provide robustness, which have been proven to be resilient to node failures even when a relatively large fraction of the nodes fail at the same time (Bharambe et al. 2008; Kavalionak et al. 2015).

In unstructured P2P DVEs, overlays lack a defined structure and are built relying on probabilistic mechanisms (as in gossip-based solutions (Carlini et al. 2012; Scholtes et al. 2008)) or according to the proximity of the peers in the virtual world (as in Voronoi-based solutions (Hu et al. 2006; Ricci et al. 2011)). Gossip overlay eventually converges to an overlay connecting those peers that are "close" according to some factor (e.g., share the same interest in a portion of the virtual world). Voronoi overlay is built by partitioning the virtual world into a Voronoi diagram (Aurenhammer 1991) and then connecting the peers accordingly (e.g., by creating a Delaunay overlay (Ricci et al. 2011)). Unstructured P2P overlays adapt quickly to sudden and unpredictable situations in the virtual worlds and are inexpensive to build and maintain. However, interest management in such networks is often done in a probabilistic manner and without strong guarantees on content retrieval. Consistency is usually managed by employing aggressive (and usually computationally costly) redundancy mechanisms, such as flooding or content replication. Regarding load balancing, DVEs based on Voronoi offer an inherent mechanism to distribute the load, as the Voronoi spatial partitioning naturally assigns regions to the peers. Finally, several approaches exploit a combination of structured and unstructured P2P overlays and are referred to as *hybrid* P2P-based DVEs (Buyukkaya et al. 2009; Kienzle et al. 2009; Yu and Vuong 2005).

Regardless of the overlay network structure (or lack of), normally the game world is divided into regions, with each peer assigned to manage one more regions. Some approaches delegate the management of the regions to any peer (Knutsson et al. 2004; Ricci et al. 2011), whereas other approaches consider a specific subset of peer (i.e., the *super peers*). Typically super peers are chosen for their hardware and bandwidth capabilities (Kim et al. 2004), either statically or by performing some kind of election mechanisms (Carlini et al. 2013; Chan et al. 2007).

Conclusion

From the perspective of research, P2P gaming has been a very thriving research field, bringing important innovations that have affected also other contexts of distributed systems, especially for the mechanisms and solutions to exploit the computational resources of the user to support an application. Despite this, P2P gaming platform outside the research context has had mild success. Initial enterprises that commercialized pure P2P gaming platforms, such as Manic Networks or DemonWare, eventually changed their core business. The main reason behind this situation is the lack of control of the game from the game published/developer. This makes extremely hard to control cheating, the performance are too dependent on the network of the players, and it is not possible to offer the users other payed services.

Today, P2P gaming solutions are utilized blended together with centralized infrastructures, to retain a degree of control on the game by the publishers. P2P gaming is then limited to only support several communications and in cases where a peer works as the server for specific multiplayer matches. A notable gaming market in which P2P solutions are currently used is the mobile and portable consoles one, for example, by the Nintendo Switch. In such systems, cheating is more complicated than on personal computers, and it is possible to exploit the proximity of the players to smooth the game.

Synonyms

Determination of orthogonal pencils of spheres.

Definitions

Introduction of Minkowski-Lorentz spaces to simplify Euclidean two- or three-dimensional problems.

Introduction

The entry deals with the Minkowski-Lorentz spaces in connection with some computer graphics computations problems. The Minkowski space is equipped of the isotropic quadratic form based on:

$$Q\left(\vec{u}\right) = x^2 + y^2 + z^2 - (c \times t)^2$$

where $\vec{u}(x, y, z, t)$ and c the speed of the light. From an n-dimensional Euclidean space $\mathcal{E}_n$ one can define the $n + 2$-dimensional Minkowski-Lorentz spaces. The computer-aided design process calls circles, spheres, and their pencils. These are basic shapes in the two- or three-dimensional Euclidean space. Thus, pencils of Euclidean circles in $\mathcal{E}_2$ or spheres in $\mathcal{E}_n$ are considered as circles in the suitable Minkowski-Lorentz space making the computation easier as the quadratic equations are seen as linear equations. Any circle in the Minkowski-Lorentz space is seen as the intersection of the unit sphere and a plane passing through the origin. The same algorithm for Euclidean circles or Euclidean spheres applies. The entry points out pencils of circles with base points in the two-dimensional space. It shows how pencils of orthogonal spheres in the Euclidean space are easily computed in the Minkowski-Lorentz space.

Some other problems, using pencils of tangent spheres in the Minkowski-Lorentz space, can be recalled: from three contact conditions (a point and an oriented plane containing this point) (Langevin et al. 2014), a one-parameter family of Dupin cyclides tangent along a common curve can be determined (see (Langevin et al. 2014)); a Dupin cyclide principal patch (Martin 1982; Srinivas et al. 1996) can be computed (Garnier and Druoton 2013a; Garnier and Druoton 2013b).

This entry is organized as follows: section "Pencils of Oriented n – 1-Spheres in ε_n" deals with the oriented circles (resp. spheres) in the usual Euclidean plane (resp. space). In Section "Linear Pencil of 2-Spheres in $L_{4,1}$," the oriented circles or spheres are represented as circles in the Minkowski-Lorentz space. In Section "Pencils of Orthogonal Spheres," from a given pencil $\mathcal{P}_1$ of circles or spheres, an other pencil $\mathcal{P}_2$ of circles or spheres is computed, where each element of $\mathcal{P}_2$ is perpendicular to an element of $\mathcal{P}_1$. The last section draws some conclusion and proposes future works.

Pencils of Oriented n – 1-Spheres in ε_n

An n – 1-sphere S with center Ω and radius r generates two n – 1-spheres S^+ (with a positive radius $\rho = r$) and S^- (with a negative radius $\rho = -r$). The n – 1-sphere S^+ is such that the unit normal vector $\vec{N}$ at the point M is in the same direction than the vector $\overrightarrow{\Omega M}$. For the n – 1-sphere S^-, the unit normal vector $\vec{N}$ at the point M has

the direction opposite to the vector $\overrightarrow{\Omega M}$. Then, the authors have the same formula in the two cases

$$\overrightarrow{\Omega M} = \rho \vec{N}. \tag{1}$$

with $|\rho| = r$. The authors can define the power of a point.

Definition 1 *Power of a point M with respect to an n – 1-sphere*

Let S *be an oriented n – 1-sphere of center Ω and of (algebraic) radius ρ. Let M be a point of* $\mathcal{E}_n$.

The power of the point M with respect to the n – 1-sphere S is the following real number:

$$\chi_{\mathrm{S}}(M) = \Omega M^2 - \rho^2 \tag{2}$$

The number $\chi_{\mathrm{S}}(M)$ does not depend on the sign of the radius ρ. The points M of the n – 1-sphere S are characterized by $\chi_{\mathrm{S}}(M) = 0$. The points M belonging to the bounded part defined by S are characterized by $\chi_{\mathrm{S}}(M) < 0$. The other points M verify $\chi_{\mathrm{S}}(M) > 0$. This notion to two spheres can be generalized.

Definition 2 *Orthogonal spheres and relative power of two spheres*

For $i \in \{1, 2\}$, *let* S_i *be an n – 1-sphere of center* Ω_i *and of radius* ρ_i. *The relative power of the two spheres* S_1 *and* S_2 *is*

$$\chi_{\mathrm{S}_1,\mathrm{S}_2} = \Omega_1\,\Omega_2^2 - \rho_1^2 - \rho_2^2 \tag{3}$$

Moreover the n – 1-spheres S_1 *and* S_2 *are orthogonal if the authors have*

$$\chi_{\mathrm{S}_1,\mathrm{S}_2} = 0 \tag{4}$$

In fact, let A be a point of the non-empty set $\mathrm{S}_1 \cap \mathrm{S}_2$. The $n-1$ spheres S_1 and S_2 are orthogonal if $\Omega_1\Omega_2 A$ is a right-angled triangle and the segment $[\Omega_1\ \Omega_2]$ is the hypotenuse of $\Omega_1\Omega_2 A$. Using the power of a point with respect to a sphere, the authors can define a pencil of spheres.

Definition 3 *Pencil of spheres*

For $i \in \{1, 2\}$, *let* S_i *be an n – 1-sphere of center* Ω_i *and of radius* ρ_i *with* $\Omega_1 \neq \Omega_2$.

Let λ_1 *and* λ_2 *be two reals not both equal to zero.*

The pencil of n – 1-spheres defined by S_1 *and* S_2 *is the set, denoted* $\lambda_1\ \mathrm{S}_1 + \lambda_2\ \mathrm{S}_2$, *containing the points M which verify*

$$\lambda_1\ \chi_{\mathrm{S}_1}(M) + \lambda_2\ \chi_{\mathrm{S}_2}(M) = 0 \tag{5}$$

The Euclidean scalar product of $\overrightarrow{\mathcal{E}_n}$ is noted •. First, the particular case $\lambda_1 + \lambda_2 = 0$ is considered. In this case, if M belongs to $\lambda_1\ \mathrm{S}_1 - \lambda_1\ \mathrm{S}_2$, Eq. (5) becomes

$$\Omega_1 M^2 - \rho_1^2 - \Omega_2 M^2 + \rho_2^2 = 0 \tag{6}$$

which is equivalent to

$$\left(\overrightarrow{\Omega_1 M} - \overrightarrow{\Omega_2 M}\right) \bullet \left(\overrightarrow{\Omega_1 M} + \overrightarrow{\Omega_2 M}\right) = \rho_1^2 - \rho_2^2$$

which can be simplified into

$$\overrightarrow{\Omega_1\,\Omega_2} \bullet \overrightarrow{IM} = \frac{\rho_1^2 - \rho_2^2}{2} \tag{7}$$

where I is the midpoint of the segment $[\Omega_1\ \Omega_2]$. Let I_0 be the point of the line $(\Omega_1\ \Omega_2)$ defined by

$$\overline{II_0} = \frac{\rho_1^2 - \rho_2^2}{2\,\overline{\Omega_1\,\Omega_2}} \tag{8}$$

where $\overline{AB}$ designates the algebraic length of the vector $\overrightarrow{AB}$. Then, $\lambda_1\ \mathrm{S}_1 - \lambda_1\ \mathrm{S}_2$ is an oriented hyperplane passing through I_0 and its unit normal vector is $\frac{1}{\overline{\Omega_1\,\Omega_2}}\overrightarrow{\Omega_1\,\Omega_2}$ or $\frac{-1}{\overline{\Omega_1\,\Omega_2}}\overrightarrow{\Omega_1\,\Omega_2}$.

If $\lambda_1 + \lambda_2 \neq 0$ and if M is a point of $\lambda_1\ \mathrm{S}_1 + \lambda_2\ \mathrm{S}_2$, Eq. (5) becomes

$$\begin{aligned}&\lambda_1\left(\overrightarrow{\Omega_1\,\Omega_{12}} + \overrightarrow{\Omega_{12}M}\right)^2\\ &\quad + \lambda_2\left(\overrightarrow{\Omega_2\,\Omega_{12}} + \overrightarrow{\Omega_{12}M}\right)^2\\ &\quad = \lambda_1\,\rho_1^2 + \lambda_2\,\rho_2^2\end{aligned} \tag{9}$$

where Ω_{12} is the barycenter of the weighted points $(\Omega_1,\ \lambda_1)$ and $(\Omega_2,\ \lambda_2)$. Formula (9) can be transformed into

$$\overrightarrow{\Omega_{12}M^2} = -\frac{\lambda_1\left(\Omega_1\,\Omega_{12}^2 - \rho_1^2\right) + \lambda_2\left(\Omega_2\,\Omega_{12}^2 - \rho_2^2\right)}{\lambda_1 + \lambda_2} \tag{10}$$

which shows that the center of the $n-1$-sphere $\lambda_1\,\mathrm{S}_1 + \lambda_2\,\mathrm{S}_2$ is the point Ω_{12} whereas the radius of the aforementioned sphere is

$$\rho_{12} = \varepsilon\sqrt{-\frac{\lambda_1\left(\Omega_1\Omega_{12}^2 - \rho_1^2\right) + \lambda_2\left(\Omega_2\,\Omega_{12}^2 - \rho_2^2\right)}{\lambda_1 + \lambda_2}} \tag{11}$$

where ε belongs to $\{-1,1\}$. The authors can state.

Theorem 1 *For $i \in \{1,\ 2\}$, let S_i be an $n-1$-sphere of center Ω_i and of radius ρ_i with $\Omega_1 \neq \Omega_2$.*

Let λ_1 and λ_2 be two reals not both equal to zero defining a pencil of $n-1$-spheres $\lambda_1\,\mathrm{S}_1 + \lambda_2\,\mathrm{S}_2$. Then:

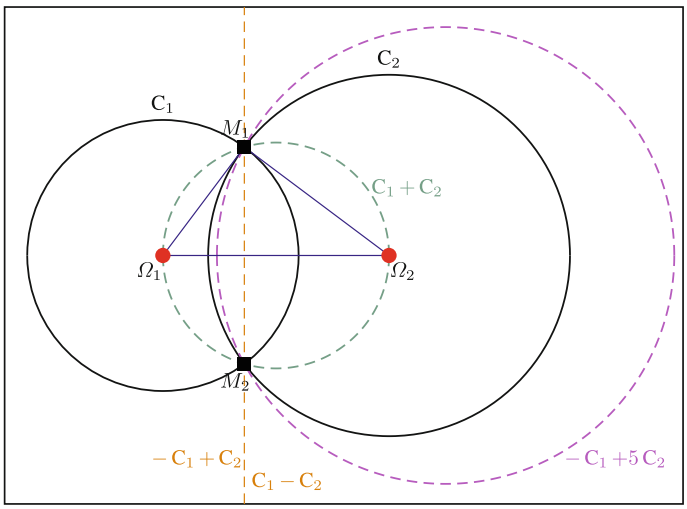
1. *If the Intersection of spheres S_1 and S_2 is a non-empty set (two points if $n = 2$, a circle if $n = 3$) C, then all the spheres (and the two oriented hyperplanes) contain the set C: the defined pencil is called a pencil with $n-2$-sphere, that is, base points if $n = 2$ and a base circle if $n = 3$,* Fig. 3a.
2. *If the spheres S_1 and S_2 are tangent at the point M_0, then all the spheres (and the two oriented hyperplanes) are tangent to S_1 and S_2 at M_0: the defined pencil is called a pencil of tangent spheres,* Fig. 3b.
3. *If the intersection of S_1 and S_2 is empty, there exist two points P_1 and P_2 on the line $(\Omega_1\ \Omega_2)$ such that the center of the sphere $\lambda_1\,\mathrm{S}_1 + \lambda_2\,\mathrm{S}_2$, $(\lambda_1 \neq -\lambda_2)$, belongs to $(\Omega_1\ \Omega_2)$ –] P_1, P_2 [: the pencil is called a pencil with limit points or a Poncelet pencil,* Fig. 3c.

Proof The proof is left to the reader and follows directly from the previous computations. ■

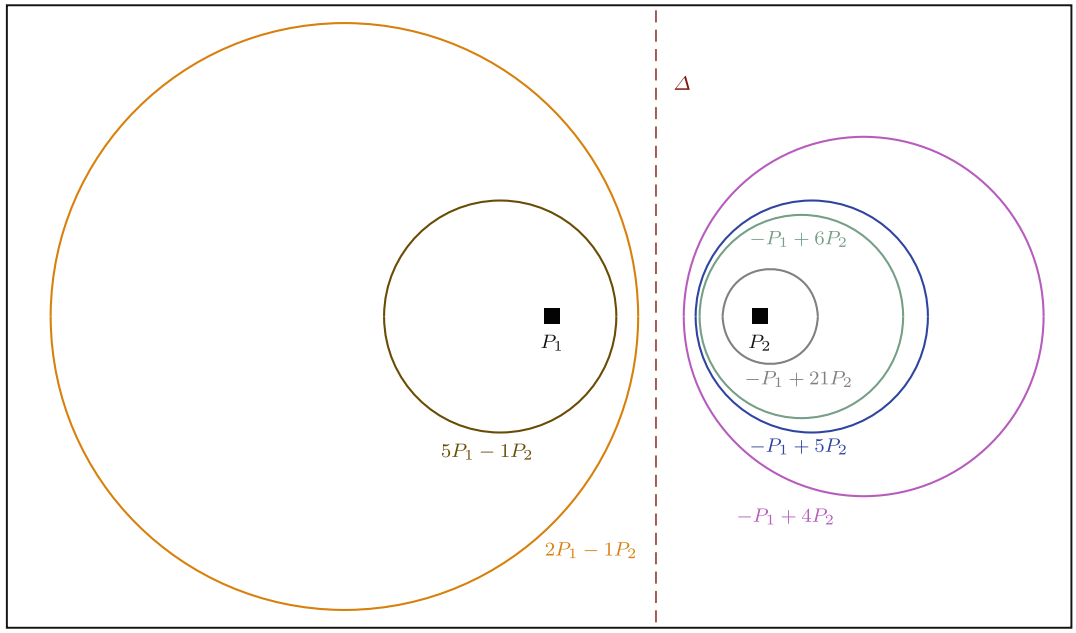
In $\mathcal{E}_2$, Fig. 1 shows a pencil of spheres with two base points. This pencil is computed from two orthogonal 1-spheres (i.e., circles), the hypotenuse of the right-angled triangle $\Omega_1\ \Omega_2\ M_1$ is the segment $[\Omega_1\ \Omega_2]$. The radii $[\Omega_1\ M_1]$ and $[\Omega_2\ M_1]$ are perpendicular.

Figure 2 shows a Poncelet pencil generated by two distinct points P_1 and P_2. Two oriented hyperplanes, the oriented perpendicular bisectors of the segment $[P_1\ P_2]$, belong to this pencil.

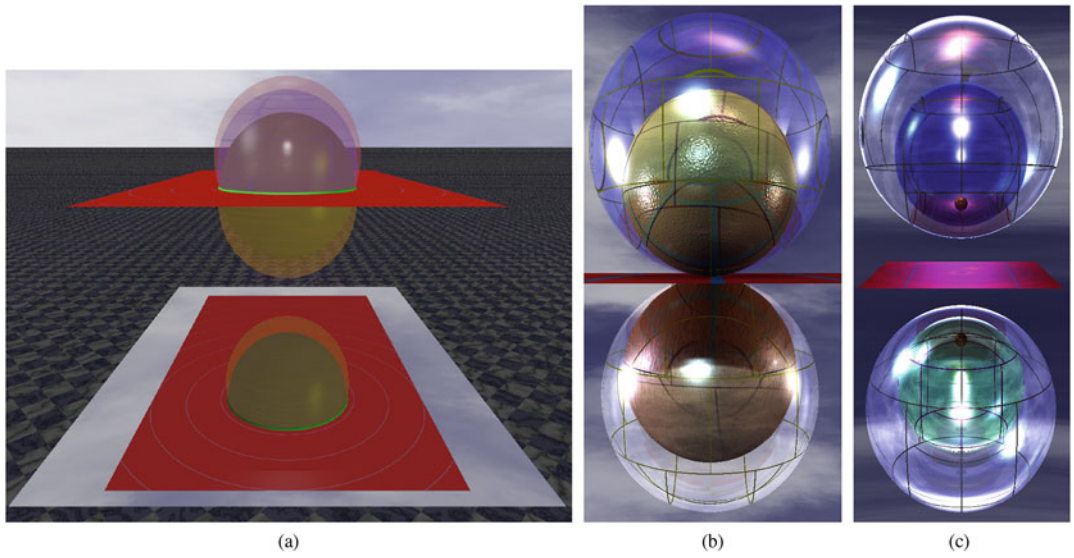
Figure 3 shows two pencils of 2-spheres in $\mathcal{E}_3$. In Fig. 3a, the pencil with a base circle is generated by two orthogonal 2-spheres: a hyperplane and a 2-sphere. The common circle is a great circle of the original 2-sphere. In Fig. 3b, the pencil is defined by two tangent spheres. In Fig. 3c, the Poncelet pencil is defined by two points.



Pencils of Spheres in the Minkowski-Lorentz Spaces, Fig. 1 Two orthogonal 1-spheres C_1 and C_2 generate a pencil of 1-spheres with base points M_1 and M_2 in $\mathcal{E}_2$. The line $(M_1\ M_2)$ defines two oriented hyperplanes $\mathrm{C}_1 - \mathrm{C}_2$ and $-\mathrm{C}_1 + \mathrm{C}_2$ belonging to this pencil



Pencils of Spheres in the Minkowski-Lorentz Spaces, Fig. 2 Two points P_1 and P_2 generate a Poncelet pencil of 1-spheres in $\mathcal{E}_2$. The line Δ is the perpendicular bisector of the segment $[P_1\ P_2]$ and defines two oriented hyperplanes $P_1 - P_2$ and $-P_1 + P_2$ of this pencil



Pencils of Spheres in the Minkowski-Lorentz Spaces, Fig. 3 Three types of 2-spheres pencils in $\mathcal{E}_3$. (**a**): a pencil of 2-spheres with base circle (in green) generated by two orthogonal sphere and hyperplane, (**b**): a pencil of tangent 2-spheres, (**c**): a Poncelet pencil

Pencils of Spheres in the Minkowski-Lorentz Spaces, Table 1 Definition of the three types of 2-planes in the Minkowski-Lorentz vector space $\overrightarrow{L_{n+1,1}}$ or in the Minkowski-Lorentz affine space $L_{n+1,1}$

Type	Two-dimensional plane $\vec{\mathcal{P}}$ or $\mathcal{P}$
Space-like	All the vectors of $\vec{\mathcal{P}}$ are space-like vectors
Time-like	Contain at least a time-like vector or exactly two non-collinear light-like ones
Light-like	Planes parallel to a tangent plane to the light cone C_l

Linear Pencil of 2-Spheres in $L_{4,1}$

A recall about the Minkowski-Lorentz space $L_{4,1}$ can be found in (Garnier et al. 2017; Garnier et al. 2019).

Section "Pencils of Oriented $n-1$-Spheres in $\mathcal{E}_n$" has shown that there exist three types of pencils of oriented $n-1$-spheres in $\mathcal{E}_n$, and there is a one-to-one relationship between the type of the pencil and the type of the 2-plane containing the aforementioned curve, Table 1. In the rest of the entry, the type of the planar curves which represents the one-parameter family of $n-1$-spheres depends on the type of the plane containing this curve.

Some properties can be stated:

Theorem 2 *Let C be the intersection between Λ^{n+1} and a two-dimensional affine plane $\mathcal{P}$ passing through Ω_{n+2}.*

- *The unit circle C looks like an ellipse and corresponds to a pencil of $n-1$-spheres with a base $n-2$-sphere,* Figs. 3a and 4a.
- *The unit circle C is the union of two parallel lines and corresponds to a pencil of tangent $n-1$-spheres,* Figs. 3b and 4b. *The point of tangency is defined by the direction of these light-like lines.*
- *The unit circle C looks like a hyperbola and corresponds to a Poncelet pencil of tangent $n-1$-spheres,* Figs. 3c and 4c.

Proof The following lemma is needed:

Lemma 1 *The representation of any pencil of $n-1$-spheres is the intersection between Λ^{n+1} and a two-dimensional affine plane $\mathcal{P}$ passing through O_{n+2}.*

Proof of Lemma 1 For $i \in \{1, 2\}$, let S_i be an $n-1$-sphere of center Ω_i and of radius ρ_i with $\Omega_1 \neq \Omega_2$. Let $\overrightarrow{\sigma_i}$ be the representation of the $n-1$-sphere S_i on Λ^{n+1}.

1/First case: $\lambda_1 + \lambda_2 = 0$

Without loss of generality, $\lambda_1 = 1 = -\lambda_2$ is used. For all point I_0, the previous relation leads to

$$\begin{cases} \overrightarrow{O_{n+2}\Omega_1}^2 = \overrightarrow{O_{n+2}I_0}^2 + 2\overrightarrow{O_{n+2}I_0} \bullet \overrightarrow{I_0\Omega_1} + \rho_1^2 \\ \overrightarrow{O_{n+2}\Omega_2}^2 = \overrightarrow{O_{n+2}I_0}^2 + 2\overrightarrow{O_{n+2}I_0} \bullet \overrightarrow{I_0\Omega_2} + \rho_2^2 \end{cases}$$

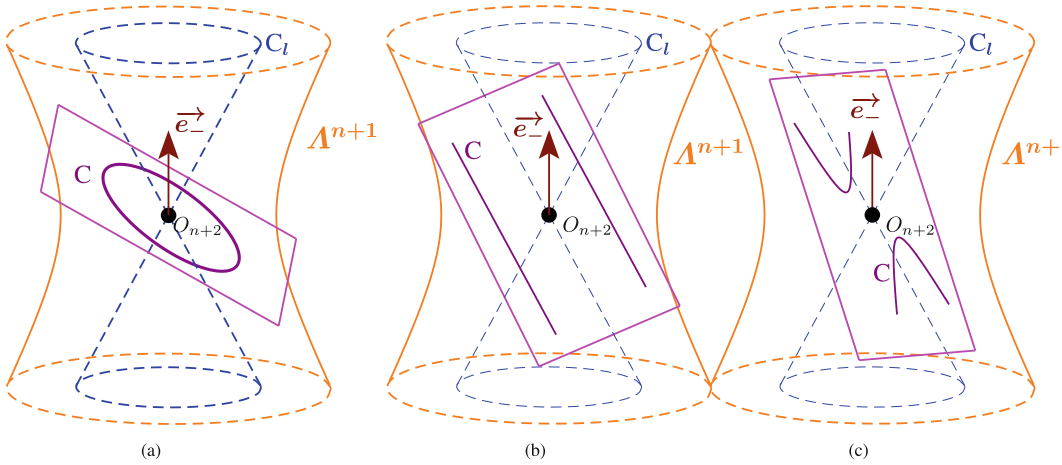
Then:

$$\begin{aligned} \frac{\rho_1}{\Omega_2\Omega_1}\overrightarrow{\sigma_1} - \frac{\rho_2}{\Omega_2\Omega_1}\overrightarrow{\sigma_2} &= \frac{1}{\Omega_2\Omega_1}\left(\overrightarrow{O_{n+2}\Omega_1} - \overrightarrow{O_{n+2}\Omega_2} + \frac{\left\|\overrightarrow{O_{n+2}\Omega_1}\right\|^2 - \rho_1^2 - \left\|\overrightarrow{O_{n+2}\Omega_2}\right\|^2 + \rho_2^2}{2}\overrightarrow{e_\infty}\right) \\ &= \frac{1}{\Omega_2\Omega_1}\overrightarrow{\Omega_2\Omega_1} + \frac{2\overrightarrow{O_{n+2}I_0} \bullet \left(\overrightarrow{I_0\Omega_1} - \overrightarrow{I_0\Omega_2}\right)}{2\,\Omega_2\Omega_1}\overrightarrow{e_\infty} \\ &= \frac{1}{\Omega_2\Omega_1}\overrightarrow{\Omega_2\Omega_1} + \left(\overrightarrow{O_{n+2}I_0} \bullet \frac{1}{\Omega_2\Omega_1}\overrightarrow{\Omega_2\Omega_1}\right)\overrightarrow{e_\infty} = \overrightarrow{\pi_1} \end{aligned}$$

and the representations $\overrightarrow{\pi_1}$ and $-\overrightarrow{\pi_1}$ of the two oriented hyperplanes of the pencil, $\overrightarrow{\sigma_1}$ and $\overrightarrow{\sigma_2}$ are co-planar.

2/Second case: $(\lambda_1 + \lambda_2)\,\lambda_1\,\lambda_2 \neq 0$

Without loss of generality, the relation $\lambda_2 = 1 - \lambda_1$ is used. The center Ω_{12} of the $n-1$-sphere



Pencils of Spheres in the Minkowski-Lorentz Spaces, Fig. 4 Three unit circles C which represent the three types of the pencils of $n-1$-spheres as intersection between the unit sphere Λ^{n+1} and a two-dimensional affine plane passing through O_{n+2}. (**a**): A pencil with base $n-2$-spheres, the type of the 2-plane is space-like, the curve looks like an ellipse. (**b**): A pencil of tangent $n-2$-spheres, the type of the 2-plane is light-like, the curve is the union of two lines. (**c**): A Poncelet pencil, the type of the 2-plane is time-like, the curve looks like an hyperbola

$\lambda_1 S_1 + (1-\lambda_1) S_2$ is the barycenter of the weighted points (Ω_1, λ_1) and $(\Omega_2, 1-\lambda_1)$. The radius of this $n-1$-sphere is given by Formula (11).

Let $\overrightarrow{\sigma_{12}}$ be the representation on Λ^{n+1} of the $n-1$-sphere $\lambda_1 S_1 + \lambda_2 S_2$ of the pencil of $n-1$-spheres generated by S_1 and S_2. Then

$$\overrightarrow{\sigma_{12}} = \frac{1}{\rho_{12}}\left(\overrightarrow{e_o} + \frac{\left\|\lambda_1\overrightarrow{O_{n+2}\Omega_1} + (1-\lambda_1)\overrightarrow{O_{n+2}\Omega_2}\right\|^2 - \rho_{12}^2}{2}\overrightarrow{e_\infty} + \lambda_1\overrightarrow{O_{n+2}\Omega_1} + (1-\lambda_1)\overrightarrow{O_{n+2}\Omega_2}\right) \tag{12}$$

The following relation

$$\rho_{12}\overrightarrow{\sigma_{12}} = \lambda_1\rho_1\overrightarrow{\sigma_1} + (1-\lambda_1)\rho_2\overrightarrow{\sigma_2} \tag{13}$$

must be proved.

The relation $\overrightarrow{e_o} = \lambda_1\overrightarrow{e_o} + (1-\lambda_1)\overrightarrow{e_o}$ leads to

$$\begin{aligned}\lambda_1\rho_1\overrightarrow{\sigma_1} + (1-\lambda_1)\rho_2\overrightarrow{\sigma_2} &= \overrightarrow{e_o} + \lambda_1\overrightarrow{O_{n+2}\Omega_1} + (1-\lambda_1)\overrightarrow{O_{n+2}\Omega_2} \\ &+ \frac{\lambda_1\left(\left\|\overrightarrow{O_{n+2}\Omega_1}\right\|^2 - \rho_1^2\right) + (1-\lambda_1)\left(\left\|\overrightarrow{O_{n+2}\Omega_2}\right\|^2 - \rho_2^2\right)}{2}\overrightarrow{e_\infty}\end{aligned} \tag{14}$$

From Formulas (12) and (14), the following relation

$$\begin{aligned}\left\|\lambda_1\overrightarrow{O_{n+2}\Omega_1}+(1-\lambda_1)\overrightarrow{O_{n+2}\Omega_2}\right\|^2-\rho_{12}^2\\ =\lambda_1\left(\left\|\overrightarrow{O_{n+2}\Omega_1}\right\|^2-\rho_1^2\right)\\ +(1-\lambda_1)\left(\left\|\overrightarrow{O_{n+2}\Omega_2}\right\|^2+\rho_2^2\right)\end{aligned}\quad(15)$$

implies that Formula (13) is true. As

$$\begin{aligned}&\left\|\lambda_1\overrightarrow{O_{n+2}\Omega_1}+(1-\lambda_1)\overrightarrow{O_3\Omega_2}\right\|^2\\ &=\lambda_1^2\overrightarrow{O_{n+2}\Omega_1}^2+(1-\lambda_1)^2\overrightarrow{O_{n+2}\Omega_2}^2\\ &\quad+2\lambda_1(1-\lambda_1)\overrightarrow{O_{n+2}\Omega_1}\bullet\overrightarrow{O_{n+2}\Omega_2}\end{aligned}$$

the last step is the computation of $-\rho_{12}^2$:

$$\begin{aligned}-\rho_{12}^2&=\lambda_1\left(\left(\overrightarrow{\Omega_1O_{n+2}}+\overrightarrow{O_{n+2}\Omega_{12}}\right)^2-\rho_1^2\right)+(1-\lambda_1)\left(\left(\overrightarrow{\Omega_2O_{n+2}}+\overrightarrow{O_{n+2}\Omega_{12}}\right)^2-\rho_2^2\right)\\ &=\lambda_1\left(\overrightarrow{\Omega_1O_{n+2}}^2+\overrightarrow{O_{n+2}\Omega_{12}}^2+2\overrightarrow{\Omega_1O_{n+2}}\bullet\overrightarrow{O_{n+2}\Omega_{12}}-\rho_1^2\right)\\ &\quad+(1+\lambda_1)\left(\overrightarrow{\Omega_2O_{n+2}}^2+\overrightarrow{O_{n+2}\Omega_{12}}^2+2\overrightarrow{\Omega_2O_{n+2}}\bullet\overrightarrow{O_{n+2}\Omega_{12}}-\rho_2^2\right)\\ &=\lambda_1\left(\overrightarrow{\Omega_1O_{n+2}}^2-\rho_1^2\right)+(1-\lambda_1)\left(\overrightarrow{\Omega_2O_{n+2}}^2-\rho_2^2\right)+\overrightarrow{O_{n+2}\Omega_{12}}^2\\ &\quad+2\left(\lambda_1\overrightarrow{\Omega_1O_{n+2}}+(1-\lambda_1)\overrightarrow{\Omega_2O_{n+2}}\right)\bullet\overrightarrow{O_{n+2}\Omega_{12}}\end{aligned}$$

and the condition given in Formula (15) becomes

$$\begin{aligned}&\left\|\lambda_1\overrightarrow{O_{n+2}\Omega_1}+(1-\lambda_1)\overrightarrow{O_{n+2}\Omega_2}\right\|^2+\overrightarrow{O_{n+2}\Omega_{12}}^2\\ &\quad-2\left(\lambda_1\overrightarrow{O_{n+2}\Omega_1}+(1-\lambda_1)\overrightarrow{O_{n+2}\Omega_2}\right)\bullet\overrightarrow{O_{n+2}\Omega_{12}}\\ &\quad=0\end{aligned}$$

which can be simplified into

$$\begin{aligned}&\left\|\lambda_1\overrightarrow{O_{n+2}\Omega_1}+(1-\lambda_1)\overrightarrow{O_{n+2}\Omega_2}\right\|^2\\ &\quad-\left(\lambda_1\overrightarrow{O_{n+2}\Omega_1}+(1-\lambda_1)\overrightarrow{O_{n+2}\Omega_2}\right)\bullet\overrightarrow{O_{n+2}\Omega_{12}}\\ &\quad=0\end{aligned}$$

(Ω_{12} is the barycenter of the weighted points (Ω_1, λ_1) and $(\Omega_2, 1-\lambda_1)$) which can be simplified into

$$\begin{aligned}&\left\|\lambda_1\overrightarrow{O_{n+2}\Omega_1}+(1-\lambda_1)\overrightarrow{O_{n+2}\Omega_2}\right\|^2\\ &\quad-\left\|\lambda_1\overrightarrow{O_{n+2}\Omega_1}+(1-\lambda_1)\overrightarrow{O_{n+2}\Omega_2}\right\|^2\\ &\quad=0\end{aligned}$$

As this last relation is still true: the relation (13) is true too.

3/Conclusion: the vectors $\overrightarrow{\sigma_{12}}$, $\overrightarrow{\sigma_1}$, and $\overrightarrow{\sigma_2}$ are always co-planar. Moreover, if $\vec{\sigma}$ represents an $n-1$-sphere of the pencil, $-\vec{\sigma}$ represents the same geometrical $n-1$-sphere of the pencil, then O_{n+2} belongs to the 2-plane containing the points σ (The orientation of the two $n-1$-spheres change.).

□

Proof of the Theorem To prove the theorem, the number of light direction is determined.

1. If the pencil is a pencil with base $n-2$-spheres, all the $n-1$-spheres of this pencil are not degenerate, the type of the 2-plane is space-like.

2. If the pencil is a pencil of tangent $n-2$-spheres, one and only one of the $n-1$-spheres of this pencil is degenerate (the point of tangency), the type of the 2-plane is light-like.
3. If the pencil is a Poncelet pencil, two distinct $n-1$-spheres of this pencil are degenerate (the limit point), the type of the 2-plane is time-like.

■

The curves in Fig. 4 are unit circle (for the Lorentz form) of center O_{n+2} because any point c which represents a nondegenerate $n-1$-sphere of a pencil verifies $\overrightarrow{O_{n+2}\sigma}^2 = 1$. The equations of these curves are given in the next subsections.

Equation of a Pencil with Base $n-2$-Sphere

Let us remark that if $n=2$, the $n-2$-sphere is the union of two points M_1 and M_2, the center of this $n-2$-sphere is the midpoint of the segment $[M_1 M_2]$, the radius of this $n-2$-sphere is $\frac{M_1M_2}{2}$. The general equation of this type of pencil can be given.

Proposition 1 *Let C be a geometrical $n-2$-sphere of $\mathcal{E}_n$ of center Ω_1 and of (positive) radius r_1.*

*Let S_1 be an $n-1$-sphere of center Ω_1 and of radius ρ_1 (*i.e.*, $|\rho_1| = r_1$).*

Let $\mathcal{P}_1$ be an oriented hyperplane containing the $n-2$-sphere C.

Let $\overrightarrow{\sigma_1}$ (resp. $\overrightarrow{\pi_1}$) be the representation of S_1 (resp. $\mathcal{P}_1$) on Λ^{n+1}.

The parametric equation of the pencil of $n-1$-spheres with base C is

$$\begin{aligned}\overrightarrow{\sigma(t)} &= \overrightarrow{O_{n+2}\sigma(t)} \\ &= \cos(t)\ \overrightarrow{\sigma_1} + \sin(t)\,\overrightarrow{\pi_1}, t \in \mathbb{R}\end{aligned} \tag{16}$$

Proof Let us recall that $\mathcal{P}_1$ and S_1 are orthogonal, that is, $\overrightarrow{\sigma_1}^{\blacksquare}\overrightarrow{\pi_1} = 0$.

From theorem 2, an $n-1$-sphere of this pencil is linear combination of two $n-1$-spheres of this pencil. So, from Formula (16), an $n-1$-sphere $\sigma(t)$ verifies

$$\begin{aligned}\overrightarrow{O_{n+2}\sigma(t)}^2 &= \left(\cos(t)\,\overrightarrow{\sigma_1} + \sin(t)\,\overrightarrow{\pi_1}\right)^2 = \cos^2(t)\underbrace{\overrightarrow{\sigma_1}^2}_{=1} + \sin^2(t)\underbrace{\overrightarrow{\pi_1}^2}_{=1} + 2\cos(t)\,\sin(t)\underbrace{\overrightarrow{\sigma_1}^{\blacksquare}\overrightarrow{\pi_1}}_{=0} \\ &= \cos^2(t) + \sin^2(t) = 1\end{aligned}$$

and the point $\sigma(t)$ belongs to an unit circle, of center O_{n+2}, of Λ^{n+1}. Moreover

$$\left\{\begin{array}{l|rcl}\overrightarrow{O_{n+2}\sigma(t)}^{\blacksquare}\overrightarrow{\sigma_1} & = & |\cos(t)| \le 1 \\ \overrightarrow{O_{n+2}\sigma(t)}^{\blacksquare}\overrightarrow{\pi_1} & = & |\sin(t)| \le 1\end{array}\right.$$

which proves that $\sigma(t)$ cuts $C = \mathrm{S}_1 \cap \mathcal{P}_1$. ■

Formula (16) leads to $\overrightarrow{\sigma(0)} = \overrightarrow{\sigma_1}$ and $\frac{\overrightarrow{d\sigma(0)}}{dt} = \overrightarrow{\pi_1}$: the vector $\overrightarrow{\pi_1}$ is the unit vector which is tangent to the circle at the point $\sigma(0)$.

An example of the representation of this type of curve using rational quadratic Bézier curves and mass points is given, more general results about mass points and rational quadratic Bézier curves can be found in (Garnier and Bécar 2017; Garnier and Bécar 2016; Garnier et al. 2017).

Let C be the circle of $\mathcal{E}_3$, in the plane $\mathcal{P}: z=0$, of center O_3 and of radius 2. The oriented sphere S_1^- of center O_3 and of radius -2 and the plane $\mathcal{P}_1^+$ oriented by the normal vector $\vec{k}$ are chosen. The representation of S_1^- is σ_1 defined by

$$\begin{aligned}\overrightarrow{O_5\sigma_1} &= -\frac{1}{2}\left(\overrightarrow{e_0} + \overrightarrow{O_3O_3} + \frac{1}{2}\left(\overrightarrow{O_3O_3} - (-2)^2\right)\overrightarrow{e_\infty}\right) \\ &= -\frac{1}{2}\left(\overrightarrow{e_0} - 2\overrightarrow{e_\infty}\right)\end{aligned}$$

whereas the representation of $\mathcal{P}_1$ is π_1 defined by

$$\overrightarrow{O_5\pi_1} = \vec{k} + \left(\overrightarrow{O_3O_3} \bullet \vec{k}\right)\overrightarrow{e_\infty} = \vec{k}$$

One can see that

$$\overrightarrow{O_5\sigma_\blacksquare}\,\overrightarrow{O_5\pi} = 0$$

On the space of spheres Λ^4, the pencil is represented by two rational quadratic Bézier curves using mass points, the first and last control points are the points σ and $-\sigma$ of the Minkowski-Lorentz affine space $L_{4,1}$ whereas the intermediate control point $\overrightarrow{\pi_1}$ is a unit space-like vector of the Minkowski-Lorentz vector space $\overrightarrow{L_{4,1}}$. In Formula (16), $t \in [0, \pi]$ and then

$$\overrightarrow{O_5\sigma(\vartheta)} = \frac{1-\vartheta^2}{1+\vartheta^2}\overrightarrow{O_5\sigma_1} + \frac{2\vartheta}{1+\vartheta^2}\overrightarrow{\pi_1} \qquad (17)$$

with $\vartheta \in \overline{\mathbb{R}}$ and $\vartheta \in \overline{\mathbb{R}^+}$ to obtain a semi-circle. To use Bezier curve, the parameter must belong to [0,1], the numerical function h is defined by⟧

$$h(u) = \frac{u}{1-u} \qquad (18)$$

and $h([0,1]) = \overline{\mathbb{R}^+}$. Let us recall the quadratic Bernstein polynomial

$$B_i(t) = \frac{2!}{i!(2-i)!}(1-t)^{2-i}t^i$$

where i belongs to {0,1,2}. Using mass points, a rational quadratic Bézier curve is defined by weighted point $(P_i,\ \omega_i)$ and/or vectors $\left(\vec{P}_i, \omega_i = 0\right)$. Let us define the two sets

$$\begin{cases} I = \{i \in \ [\![0,1]\!] \ \mid \omega_i \neq 0\} \\ J = \{i \in \ [\![0,1]\!] \ \mid \omega_i = 0\} \end{cases}$$

and the denominator

$$\omega_f(t) = \sum_{i\in I}\omega_i \times B_i(t)$$

Let t_0 in [0, 1]. If $\omega_f(t_0) \neq 0$, for any point O, the element of the Bézier curve is a weighted point $M(t_0)$ defined by

$$\overrightarrow{OM(t_0)} = \frac{1}{\omega_f(t_0)}\sum_{i\in I}\omega_i B_i(t_0)\overrightarrow{OP_i} + \frac{1}{\omega_f(t_0)}\sum_{i\in J}B_i(t_0)\overrightarrow{P_i} \qquad (19)$$

and if $\omega_f(t_0) = 0$, the element of the Bézier curve is the vector $\overrightarrow{u(t_0)}$ defined by

$$\overrightarrow{u(t_0)} = \sum_{i\in I}\omega_i B_i(t_0)\overrightarrow{OP_i} + \sum_{i\in J}B_i(t_0)\overrightarrow{P_i} \qquad (20)$$

Formulas (17) and (18) lead to

$$\begin{aligned}
\overrightarrow{O_{n+2}\sigma(h(u))} &= \frac{1-\left(\frac{u}{1-u}\right)^2}{1+\left(\frac{u}{1-u}\right)^2}\overrightarrow{O_5\sigma_1} + \frac{2\frac{u}{1-u}}{1+\left(\frac{u}{1-u}\right)^2}\overrightarrow{\pi_1} \\
&= \frac{1-2u+u^2-u^2}{1-2u+u^2+u^2}\overrightarrow{O_5\sigma_1} + \frac{2u(1-u)}{1-2u+u^2+u^2}\overrightarrow{\pi_1} \\
&= \frac{1}{B_0(u)+B_2(u)}\left((B_0(u)-B_2(u))\overrightarrow{O_5\sigma_1} + B_1(u)\overrightarrow{\pi_1}\right) \\
&= \frac{1}{B_0(u)+B_2(u)}\left(B_0(u)\overrightarrow{O_5\sigma_1} + B_1(u)\overrightarrow{\pi_1} + B_2(u)\overrightarrow{O_5\sigma_-}\right)
\end{aligned}$$

P

Pencils of Spheres in the Minkowski-Lorentz Spaces, Table 2 Spheres of a pencil of 2-spheres with base circle

Value	Point $\sigma(t)$	Sphere in $\mathcal{E}_3$
$t=0$	$\left(-\frac{1}{2};0;0;0;1\right)=-\frac{1}{2}\left(1;0;0;0;\frac{1}{2}\left(-(-2)^2\right)\right)$	Center: (0; 0; 0), radius − 2
$t=\frac{1}{4}$	$\left(-\frac{2}{5};0;0;-\frac{3}{5};\frac{4}{5}\right)=\frac{1}{-\frac{3}{2}}\left(1;0;0;-\frac{3}{2};-2\right)$	Center : $\left(0;0;-\frac{3}{2}\right)$, radius $-\frac{5}{2}$
$t=\frac{1}{2}$	(0; 0; 0; 1; 0)	Point (0; 0; 0), normal vector $\vec{k}$
$t=\frac{3}{4}$	$\left(\frac{2}{5};0;0;\frac{3}{5};-\frac{4}{5}\right)=\frac{1}{\frac{3}{2}}\left(1;0;0;\frac{3}{2};-2\right)$	Center : $\left(0;0;\frac{3}{2}\right)$, radius $\frac{5}{2}$
$t=1$	$\left(\frac{1}{2};0;0;0;1\right)=\frac{1}{2}\left(1;0;0;0;\frac{1}{2}\left(-(2)^2\right)\right)$	Center: (0; 0; 0), radius 2

where σ_- is the symmetrical of σ_1 with respect to O_5. Then, the control points of the Bézier curve are $(\sigma_1, 1)$, $\left(\overrightarrow{\pi_1};0\right)$, and $(\sigma_-, 1)$. The control points of the Bézier curve which model the second semi-circle are $(\sigma_1, 1)$, $\left(-\overrightarrow{\pi_1};0\right)$, and $(\sigma_-, 1)$. After some simplifications, $\sigma(t)$ is defined by

$$\overrightarrow{O_5\sigma(t)}=\frac{1}{1-2t+t^2}\left(\frac{2t-1}{2}\overrightarrow{e_0}+2t(1-t)\vec{k}+(1-2t)\overrightarrow{e_\infty}\right)$$

and some 2-spheres are drawn, see Table 2 and Fig. 5.

For example, $t=\frac{1}{4}$ leads to $\frac{1}{2}\left(\left(-\frac{3}{2}\right)^2-\left(-\frac{5}{2}\right)^2\right)=-2$. In fact, if $t\neq\frac{1}{2}$, the radius of the corresponding $n-1$-sphere is

$$\frac{1}{1-2t+2t^2}\times\frac{2t-1}{2}=\frac{1}{(1-t)^2+t^2}\times\frac{2t-1}{2}$$

and the change of the orientation of the spheres is obtained for $t=\frac{1}{2}$, that is, when an $n-1$-sphere of the pencil is an hyperplane.

Equations of a Poncelet Pencil

In the same way as in the previous paragraph, a parameterization of a Poncelet Pencil on Λ^{n+1} can be given.

Proposition 2 *Let M_0 and M_2 be two limit points of a Poncelet pencil of $n-1$-spheres $S(t)$.*

Let $\overrightarrow{m_0}$ and $\overrightarrow{m_2}$ the light-like vectors in the Minkowski-Lorentz vector space $\overrightarrow{L_{n+1,1}}$ which represent the points M_0 and M_2. A parametric equation of a Poncelet pencil is

$$\overrightarrow{\sigma(t)}=\overrightarrow{O_{n+2}\sigma(t)}=t\frac{1}{M_2M_0}\overrightarrow{m_1}-\frac{1}{t}\frac{1}{M_2M_0}\overrightarrow{m_2},t\in\mathbb{R}^* \quad (21)$$

or

$$\overrightarrow{\sigma_{hyp}(t)}=\overrightarrow{O_{n+2}\sigma_{hyp}(t)}=\frac{1}{\cos(t)}\frac{1}{M_2M_0}\left(\overrightarrow{m_0}-\overrightarrow{m_2}\right)+\frac{\tan(t)}{M_2M_0}\left(\overrightarrow{m_0}+\overrightarrow{m_2}\right) \quad (22)$$

where t belongs to $[0,\ 2\pi]-\left\{\frac{\pi}{2},\frac{3\pi}{2}\right\}$, the type of the vector $\overrightarrow{m_0}-\overrightarrow{m_2}$ (resp. $\overrightarrow{m_0}+\overrightarrow{m_2}$) is space-like (resp. time-like).

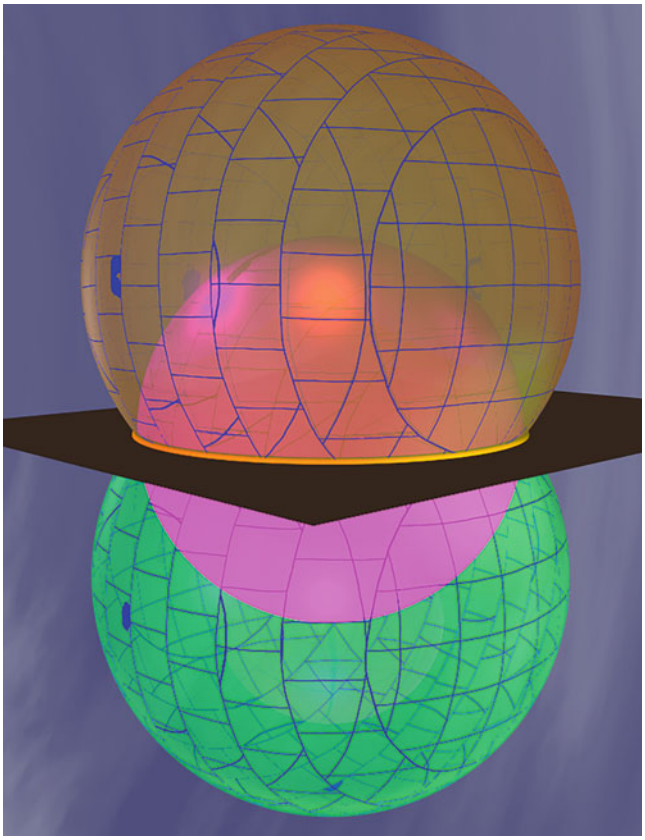
Proof Using Theorem 2, any sphere of this pencil is a linear combination of the two light-like vectors $\overrightarrow{m_0}$ and $\overrightarrow{m_2}$ with

$$\overrightarrow{m_0}=\overrightarrow{e_o}+\overrightarrow{M_0}+\frac{1}{2}\left\|\overrightarrow{M_0}\right\|^2\overrightarrow{e_\infty}$$

and

$$\overrightarrow{m_2}=\overrightarrow{e_o}+\overrightarrow{M_2}+\frac{1}{2}\left\|\overrightarrow{M_2}\right\|^2\overrightarrow{e_\infty}$$

Moreover:



Pencils of Spheres in the Minkowski-Lorentz Spaces, Fig. 5 Some spheres of a pencil of spheres with base circle modeled on the space of spheres Λ^4 by a rational quadratic Bézier curve representing a semicircle

$$\overrightarrow{m_0} \blacksquare \overrightarrow{m_2} = \left(\overrightarrow{e_o} + \overrightarrow{O_3M_0} + \frac{1}{2}\left\|\overrightarrow{O_3M_0}\right\|^2 \overrightarrow{e_\infty}\right) \blacksquare \left(\overrightarrow{e_o} + \overrightarrow{O_3M_2} + \frac{1}{2}\left\|\overrightarrow{O_3M_2}\right\|^2 \overrightarrow{e_\infty}\right)$$
$$= \overrightarrow{O_3M_0} \bullet \overrightarrow{O_3M_2} - \frac{1}{2}\overrightarrow{O_3M_0}^2 - \frac{1}{2}\overrightarrow{O_3M_2}^2 = -\frac{1}{2}\left(\overrightarrow{O_3M_0} - \overrightarrow{O_3M_2}\right)^2 = -\frac{1}{2}\overrightarrow{M_2M_0}^2$$

The plane defined by the curve, Formula (21) or (22), contains two light-like vectors, so the type of this plane is time-like. The last step consists in showing that $\sigma(t)$ and $\sigma_{hyp}(t)$ belong to Λ^{n+1}. As

$$\vec{\sigma}(t)^2 = \left(t\frac{1}{M_2M_0}\overrightarrow{m_1} - \frac{1}{t}\frac{1}{M_2M_0}\overrightarrow{m_2}\right)^2 = \frac{1}{M_2M_1^2}\left(t^2\overrightarrow{m_0}^2 - 2\overrightarrow{m_0} \blacksquare \overrightarrow{m_2} + \frac{1}{t^2}\overrightarrow{m_2}^2\right)$$
$$= \frac{-2}{M_2M_0^2}\left(-\frac{1}{2}\overrightarrow{M_2M_0}^2\right) = 1.$$

$\sigma(t)$ belongs to Λ^{n+1}. □

Concerning the second equation, the relations

$$\left(\overrightarrow{m_0} + \overrightarrow{m_2}\right)^2 = \overrightarrow{m_0}^2 + 2\,\overrightarrow{m_0} \blacksquare \overrightarrow{m_2} + \overrightarrow{m_2}^2 = -\overrightarrow{M_2M_0}^2 < 0 \tag{23}$$

and

$$\left(\overrightarrow{m_0} - \overrightarrow{m_2}\right)^2 = \overrightarrow{m_0}^2 - 2\,\overrightarrow{m_0} \blacksquare \overrightarrow{m_2} + \overrightarrow{m_2}^2 = \overrightarrow{M_2M_0}^2 > 0 \tag{24}$$

lead to

$$\begin{aligned}\overrightarrow{\sigma_{hyp}}(t)^2 &= \left(\frac{1}{\cos(t)}\frac{1}{M_2M_0}\left(\overrightarrow{m_0} - \overrightarrow{m_2}\right) + \mathrm{sh}(t)\frac{1}{M_2M_0}\left(\overrightarrow{m_0} + \overrightarrow{m_2}\right)\right)^2 \\ &= \frac{1}{M_2M_0^2}\left(\frac{1}{\cos^2(t)}\overrightarrow{M_2M_0}^2 - \tan^2(t)\overrightarrow{M_2M_0}^2\right) + \frac{2}{M_2M_0^2}\frac{\tan(t)}{\cos(t)}\left(\underbrace{\overrightarrow{m_0}^2}_{=0} - \underbrace{\overrightarrow{m_2}^2}_{=0}\right) \\ &= \frac{1}{\cos^2(t)} - \tan^2(t) = 1\end{aligned}$$

and $\sigma_{hyp}(t)$ belongs to Λ^{n+1}. ■

From Formula (21) and using Formula (18), the expression of the Bézier curve is

$$\begin{aligned}\overrightarrow{O_{n+2}\sigma(h(u))} &= \frac{u}{1-u}\frac{1}{M_2M_0}\overrightarrow{m_0} - \frac{1-u}{u}\frac{1}{M_2M_0}\overrightarrow{m_2} \\ &= \frac{u^2}{u(1-u)}\frac{1}{M_2M_0}\overrightarrow{m_0} - \frac{(1-u)^2}{u(1-u)}\frac{1}{M_2M_0}\overrightarrow{m_2} \\ &= \frac{1}{2u(1-u)}\left((1-u)^2\frac{2}{M_2M_0}\overrightarrow{m_2} + 2u(1-u)\overrightarrow{O_{n+2}O_{n+2}} - u^2\frac{2}{M_2M_0}\overrightarrow{m_0}\right) \\ &= \frac{1}{\frac{M_2M_0}{2}2u(1-u)}\left(B_0(u)\overrightarrow{m_2} + \frac{M_2M_0}{2}B_1(u)\overrightarrow{O_{n+2}O_{n+2}} - B_2(u)\overrightarrow{m_0}\right)\end{aligned}$$

and the control mass points of this rational quadratic Bézier curve are $\left(\overrightarrow{m_2}, 0\right)$, $\left(O_{n+2}, \frac{M_2M_0}{2}\right)$, and $\left(-\overrightarrow{m_0}, 0\right)$. This Bézier curve represents a branch of a unit circle which looks like a rectangular hyperbola. The second branch is modeled by a rational quadratic Bézier curve of control mass points $\left(\overrightarrow{m_2}, 0\right)$, $\left(O_{n+2}, -\frac{M_2M_0}{2}\right)$ and $\left(-\overrightarrow{m_0}, 0\right)$. In (Garnier and Bécar 2017; Garnier and Bécar 2016), a branch of a hyperbola in the usual Euclidean affine space is modeled by a rational quadratic Bézier curve of control mass points $\left(\overrightarrow{W_0}, 0\right)$, (Ω_1, ω_1), and $\left(\overrightarrow{W_2}, 0\right)$, where $\overrightarrow{W_0}$ and $\overrightarrow{W_2}$ are unit vectors and Ω is the center of the aforementioned hyperbola. If the norm of

these vectors is changed, the value of the weight ω_1 is modified. In this case in the Minkowski-Lorentz space, the second control point is the center of the circle, but the other control mass points are light-like vectors and then

$$\forall \lambda \in \mathbb{R}^*, \quad \left(\lambda \overrightarrow{m_0}\right)^2 = \left(\lambda \overrightarrow{m_2}\right)^2 = \overrightarrow{m_0}^2 = \overrightarrow{m_2}^2 = 0$$

it is not possible to distinguish two parallel light-like vector using their norms. So, the following condition is introduced.

Condition 1

If a light-like vector $\overrightarrow{m_0}$ is not $\overrightarrow{e_\infty}$, it represents a point of the Euclidean affine space $\mathcal{E}_n$ and then its first component is equal to 1.

The rational quadratic Bézier expression is simplified

$$\begin{aligned}\overrightarrow{O_{n+2}\sigma(u)} &= \frac{B_0(u)}{\omega_1 B_1(u)}\left(\overrightarrow{e_0} + \overrightarrow{O_3M_0} + \frac{\overrightarrow{M_0}^2}{2}\overrightarrow{e_\infty}\right) - \frac{B_2(t)}{\omega_1 B_1(t)}\left(\overrightarrow{e_0} + \overrightarrow{O_3M_2} + \frac{\overrightarrow{M_2}^2}{2}\overrightarrow{e_\infty}\right)\\ &= \frac{1}{\omega_1 B_1(t)}\left((B_0(t) - B_2(t))\overrightarrow{e_0} + \left(B_0(t)\frac{\overrightarrow{M_0}^2}{2} - B_2(t)\frac{\overrightarrow{M_2}^2}{2}\right)\overrightarrow{e_\infty} + B_0(t)\overrightarrow{O_3M_0} - B_2(t)\overrightarrow{O_3M_2}\right)\end{aligned}$$

Let us consider the two points $M_0(-2; 0; 0)$ and M_2 (2; 0; 0) of $\mathcal{E}_3$. Let us choose $\omega_1 = 2$. As $\overrightarrow{O_3M_2} = -\overrightarrow{O_3M_0}$ and $O_3M_0 = 2$, $\sigma(t)$ is defined by

$$\overrightarrow{O_5\sigma(t)} = \frac{1-2t}{4t(1-t)}\left(\overrightarrow{e_0} + 2\overrightarrow{e_\infty}\right) + \frac{1-2t+2t^2}{4t(1-t)}\overrightarrow{O_3M_0}$$

and some spheres are computed in Table 3 and drawn in Fig. 6. For $t = 0$ (resp. $t = 1$), the vector $\overrightarrow{m_0}$ (resp. $\overrightarrow{m_2}$) which represents the point M_0 (resp. M_2) are computed.

Equation of a Pencil of Tangent $n-1$-Spheres

Let us recall the following formula computed in (Garnier et al. 2019)

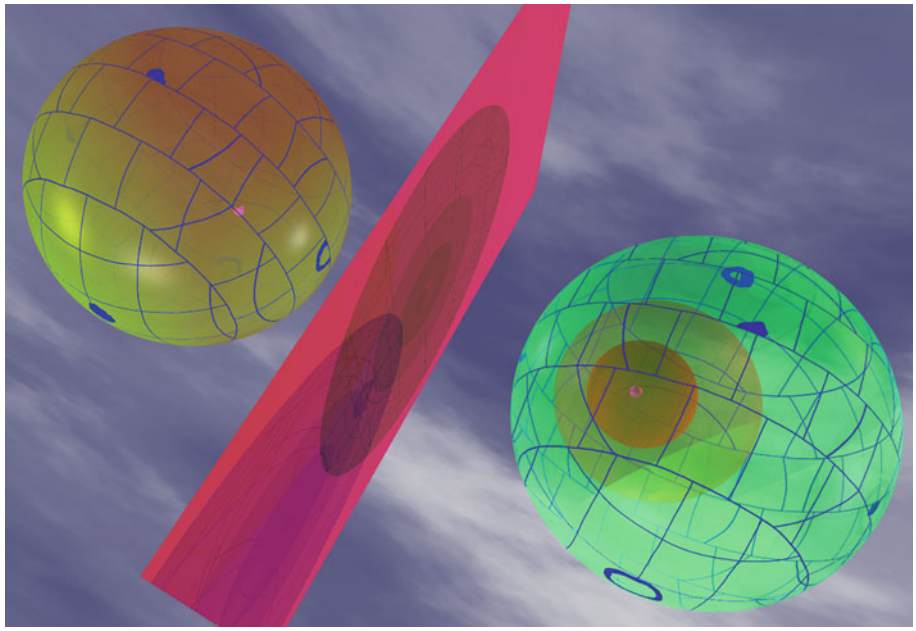
$$\overrightarrow{\sigma_1} \blacksquare \overrightarrow{\sigma_2} = -\frac{1}{2\rho_1\rho_2}\chi_{S_1,S_2} \tag{25}$$

where χ_{S_1,S_2} is obtained from Formula (3).

Let σ_1 and σ_2 be the representations of two $n-1$-spheres of $\mathcal{E}_n$ such that the spheres are tangent at the point M. Formulas (1) and (25) lead to

Pencils of Spheres in the Minkowski-Lorentz Spaces, Table 3 Spheres of a Poncelet pencil defined by two points in $\mathcal{E}_3$

Value	Point $\sigma(t)$	Sphere in $\mathcal{E}_3$
$t = \frac{1}{10}$	$\left(\frac{20}{9}; -\frac{41}{9}; 0; 0; \frac{40}{9}\right) = \frac{1}{\frac{9}{20}}\left(1; -\frac{41}{20}; 0; 0; 2\right)$	Center: $\left(-\frac{41}{20}; 0; 0\right)$, radius $\frac{9}{20}$
$t = \frac{1}{6}$	$\left(\frac{6}{5}; -\frac{13}{5}; 0; 0\frac{12}{5}\right) = \frac{1}{\frac{5}{6}}\left(1; -\frac{13}{6}; 0; 0; 2\right)$	Center: $\left(-\frac{13}{6}; 0; 0\right)$, radius $\frac{5}{6}$
$t = \frac{1}{4}$	$\left(\frac{2}{3}; -\frac{5}{3}; 0; 0; \frac{4}{3}\right) = \frac{1}{\frac{3}{2}}\left(1; -\frac{5}{2}; 0; 0; 2\right)$	Center: $\left(-\frac{5}{2}; 0; 0\right)$, radius $\frac{3}{2}$
$t = \frac{1}{2}$	(0 1 −1; 0; 0; 0)	Point (0; 0; 0), normal vector $-\vec{\imath}$
$t = \frac{3}{4}$	$\left(-\frac{2}{3}; -\frac{5}{3}; 0; 0; -\frac{4}{3}\right) = \frac{1}{-\frac{3}{2}}\left(1; \frac{5}{2}; 0; 0; 2\right)$	Center: $\left(\frac{5}{2}; 0; 0\right)$, radius $-\frac{3}{2}$



Pencils of Spheres in the Minkowski-Lorentz Spaces, Fig. 6 Some 2-spheres of a Poncelet pencil in $\mathcal{E}_3$ modeled by a rational quadratic Bézier curve with control mass points in the Minkowski-Lorentz space

$$\begin{aligned}\overrightarrow{\sigma_1}\blacksquare\,\overrightarrow{\sigma_1} &= -\frac{1}{2\rho_1\rho_2}\chi_{S_1,S_2} = \frac{1}{2\rho_1\rho_2}\left(-\overrightarrow{\Omega_2\Omega_1}^2+\rho_1^2+\rho_2^2\right) = \frac{1}{2\rho_1\rho_2}\left(-\left(\overrightarrow{\Omega_2M}+\overrightarrow{M\Omega_1}\right)^2+\rho_1^2+\rho_2^2\right)\\ &= \frac{1}{2\rho_1\rho_2}\left(-\overrightarrow{\Omega_2M}^2-2\overrightarrow{\Omega_2M}\blacksquare\,\overrightarrow{M\Omega_1}-\overrightarrow{M\Omega_2}^2+\rho_1^2+\rho_2^2\right)\\ &= \frac{1}{2\rho_1\rho_2}\left(-\rho_2^2\underbrace{\overrightarrow{N_2}^2}_{=1}+2\rho_1\rho_2\,\overrightarrow{N_2}\blacksquare\,\overrightarrow{N_1}-\rho_1^2\underbrace{\overrightarrow{N_1}^2}_{=1}+\rho_1^2+\rho_2^2\right) = \overrightarrow{N_2}\blacksquare\,\overrightarrow{N_1}\in\{-1,1\}\end{aligned}$$

Moreover, the relation

$$\begin{aligned}\overrightarrow{\sigma_1\sigma_2}^2 &= \left(\overrightarrow{\sigma_1O_{n+2}}+\overrightarrow{O_{n+2}\sigma_2}\right)^2 = \left(\overrightarrow{\sigma_2}-\overrightarrow{\sigma_1}\right)^2\\ &= \overrightarrow{\sigma_1}^2-2\overrightarrow{\sigma_1}\blacksquare\,\overrightarrow{\sigma_2}+\overrightarrow{\sigma_2}^2 = 2\left(1-\overrightarrow{\sigma_1}\blacksquare\,\overrightarrow{\sigma_2}\right)\end{aligned} \tag{26}$$

permits to state

Proposition 3 *Let S_1 and S_2 be two oriented $n-1$-spheres of the Euclidean affine space $\mathcal{E}_n$.*

Let $\overrightarrow{\sigma_1}$ (resp. $\overrightarrow{\sigma_2}$) be the representation of S_1 (resp. S_2) on Λ^{n+1}.

The $n-1$-spheres S_1 and S_2, having the same orientation, are tangent if and only if

$$\overrightarrow{\sigma_1\sigma_2}^2 = 0$$

The important result is that, on Λ^{n+1}, **a light line (called light ray too) is the representation of tangent oriented $n-1$-spheres, having the same orientation, at the same point. The direction of the vector $\overrightarrow{\sigma_1\sigma_2}$ gives the point of tangency between the two $n-1$-spheres** and we can give the equation of a pencil of tangent $n-1$-spheres:

Proposition 4 *Let S_1 be an $n-1$-sphere and M_1 a point on S_1.*

Let $\overrightarrow{\sigma_1}$ (resp. $\overrightarrow{m_1}$) be the representation of S_1 (resp. M_1) on Λ^{n+1}.

The parametric equation of the representation of the pencil of $n-1$-spheres tangent to the sphere S_1 is

$$\overrightarrow{\sigma(t)} = \overrightarrow{O_{n+2}\sigma(t)} = \varepsilon\overrightarrow{\sigma_1} + t\overrightarrow{m_1}, t \in \mathbb{R} \qquad (27)$$

where ε belongs to $\{-1, 1\}$.

Pencils of Orthogonal Spheres

In this section, from a given pencil $\mathcal{P}_1$ of spheres, a pencil $\mathcal{P}_2$ of spheres is computed such as any sphere of the pencil $\mathcal{P}_1$ is orthogonal to all the spheres of the pencil $\mathcal{P}_2$. Using Minkowski-Lorentz space, the solution of this problem is very simple: each pencil is defined by a 2-plane $\mathcal{P}_i, i \in \{1, 2\}$ passing through the point O_{n+2}, it is enough that the 2-planes $\mathcal{P}_1$ and $\mathcal{P}_2$ are perpendicular.

If $n = 2$, there is no choice, see Table 4, whereas if $n = 3$, there is a degree of freedom using an line Δ orthogonal to the 2-planes $\mathcal{P}_1$ and $\mathcal{P}_2$, see Table 5.

For $i \in \{1, 2\}$, the reader can note that if the center of the conic $\mathcal{P}_i \cap \Lambda^4$ is $\Omega_i \neq O_5$ with the two following conditions:

$$\begin{cases} \overrightarrow{O_5\Omega_1}^2 \neq 0 \\ \overrightarrow{O_5\Omega_2} = \dfrac{1}{\overrightarrow{O_5\Omega_1}^2}\overrightarrow{O_5\Omega_1} \end{cases} \qquad (28)$$

Table 5 gives the properties of Dupin cyclides where base circle (resp1 Poncelet) (resp2 tangent spheres) is replaced by ring (resp. horned or spindle) (resp2 one-singularity spindle or singly horned). One can note the conditions given in Formula (28) lead to

$$\overrightarrow{O_5\Omega_2}\cdot\overrightarrow{O_5\Omega_1} = 1$$

Example with a Pencil of Line Passing Through a Point in $\mathcal{E}_2$

Let $\mathcal{P}_t$ be the pencil of lines defined by the point Ω_0 (1, 1) and the normal vector $\vec{N}(\cos(t), \sin(t))$. The representation of the pencil $\mathcal{P}_t$ in the Minkowski-Lorentz space $L_{3,1}$ is

$$\vec{\Pi}_0(t)\,(0, \cos(t), \sin(t), \cos(t) + \sin(t))$$

As $\vec{\Pi}_0(0)\,(0, 1, 0, 1)$ and $\vec{\Pi}_0\left(\frac{\pi}{2}\right)(0, 0, 1, 1)$, the computation

Pencils of Spheres in the Minkowski-Lorentz Spaces, Table 4 Pencils of orthogonal spheres in $\mathcal{E}_2$

Type of $\mathcal{P}_1$	Type of $\mathcal{P}_1$	Type of $\mathcal{P}_2$	Type of $\mathcal{P}_2$
Base circle	Space-like	Time-light	Poncelet
Poncelet	Time-light	Space-like	Base circle

Pencils of Spheres in the Minkowski-Lorentz Spaces, Table 5 Pencils of orthogonal spheres in $\mathcal{E}_3$

Type of $\mathcal{P}_1$	Type of $\mathcal{P}_1$	Type of the line Δ	Type of $\mathcal{P}_2$	Type of $\mathcal{P}_2$
Base circle	Space-like	Space-like	Time-light	Poncelet
		Time-light	Space-like	Base circle
		Light-like	Light-like	Tangent spheres
Poncelet	Time-light	Space-like	Space-like	Base circle
Tangent spheres	Light-like	Light-like	Space-like	Base circle
		Space-like	Light-like	Tangent spheres

$$\vec{\Pi}_0(0)\blacksquare\,\vec{\Pi}_0\left(\frac{\pi}{2}\right)=0$$

permits to simplify the representation of the pencil $\mathcal{P}_t$ as follows

$$\vec{\Pi}_0(t)=\cos(t)\vec{\Pi}_0(0)+\sin(t)\vec{\Pi}_0\left(\frac{\pi}{2}\right)$$

and the type of the 2-plane $\mathcal{P}_1$ containing the point $\Pi_0(t)$ is space-like. Then, the second pencil is defined by a 2-plane $\mathcal{P}_2$ passing through O_4 and perpendicular to the plane $\mathcal{P}_1$. Immediately, one can note

$$\vec{\Pi}_0(0)\blacksquare\,\overrightarrow{e_\infty}=\vec{\Pi}_0\left(\frac{\pi}{2}\right)\blacksquare\,\overrightarrow{e_\infty}=0$$

The representation of the point Ω_0 is $\overrightarrow{o_0}$ (1,1,1,1) and a similar result

$$\vec{\Pi}_0(0)\blacksquare\,\overrightarrow{o_0}=\vec{\Pi}_0\left(\frac{\pi}{2}\right)\blacksquare\,\overrightarrow{o_0}=0$$

is obtained. So, the plane $\mathcal{P}_2$ is a time-like plane defined by O_4, $\overrightarrow{o_0}$, and $\overrightarrow{e_\infty}$. The second pencil is defined by

$$\left(u\overrightarrow{o_0}+v\overrightarrow{e_\infty}\right)^2=1$$

which leads to

$$2uv\overrightarrow{o_0}\blacksquare\,\overrightarrow{e_\infty}=1$$

The computation $\overrightarrow{o_0}\blacksquare\,\overrightarrow{e_\infty}=-1$ leads to

$$v=-\frac{1}{2u}$$

and the representation of the second pencil is

$$\begin{aligned}\vec{\sigma}(t)&=u\overrightarrow{o_0}-\frac{1}{2u}\overrightarrow{e_\infty}\\&=u\overrightarrow{e_o}+u\overrightarrow{e_1}+u\overrightarrow{e_2}+\frac{2u^2-1}{2u}\overrightarrow{e_\infty}\end{aligned}$$

which leads to a pencil of concentric circles of center Ω_0, and of radius $r_u=\frac{1}{u}$. In fact, this pencil is a Poncelet pencil with a limit point at the infinity, see Fig. 7.

The reader can note that if the first pencil is a pencil of parallel lines $\mathcal{L}_{1,i}$, the second pencil is a pencil of parallel lines $\mathcal{L}_{2,j}$ and for any i and j, the lines $\mathcal{L}_{1,i}$ and $\mathcal{L}_{2,j}$ are perpendicular.

Example with a Pencil of Circles Which Base Points in ε_2

Let $\mathcal{P}_t$ be the pencil of circles with base points M_1 (0, 3) and M_2 (0, −1). Let Ω_0 (1; 1) be the midpoint of the segment $[M_1\ M_2]$. Let $\overrightarrow{\sigma_0}\left(\frac{1}{2},\frac{1}{2},\frac{1}{2},\frac{-1}{2}\right)$ (resp. $\overrightarrow{\pi_0}(0,1,0,1)$) be the representation in the Minkowski-Lorentz space $\mathrm{L}_{3,1}$ of the circle of diameter $[M_1\ M_2]$ (resp. the line defined by the point Ω_0 and the normal vector $\frac{1}{M_1M_2}\overrightarrow{M_1M_2}$). The representation of the pencil $\mathcal{P}_t$ in $\mathrm{L}_{3,1}$ is

$$\vec{\sigma}(t)=\cos(t)\overrightarrow{\sigma_0}+\sin(t)\overrightarrow{\pi_0}$$

The representations of M_1 and M_2 in $\mathrm{L}_{3,1}$ are

$$\begin{cases}\overrightarrow{m_1}(1,1,3,5)\\ \overrightarrow{m_2}(1,1,-1,1)\end{cases}$$

with

$$\overrightarrow{m_1}\blacksquare\,\overrightarrow{\sigma_0}=\overrightarrow{m_1}\blacksquare\,\overrightarrow{\pi_0}=\overrightarrow{m_2}\blacksquare\,\overrightarrow{\sigma_0}=\overrightarrow{m_2}\blacksquare\,\overrightarrow{\pi_0}=0$$

The second pencil is defined by

$$\left(u\overrightarrow{m_1}+v\overrightarrow{m_2}\right)^2=1$$

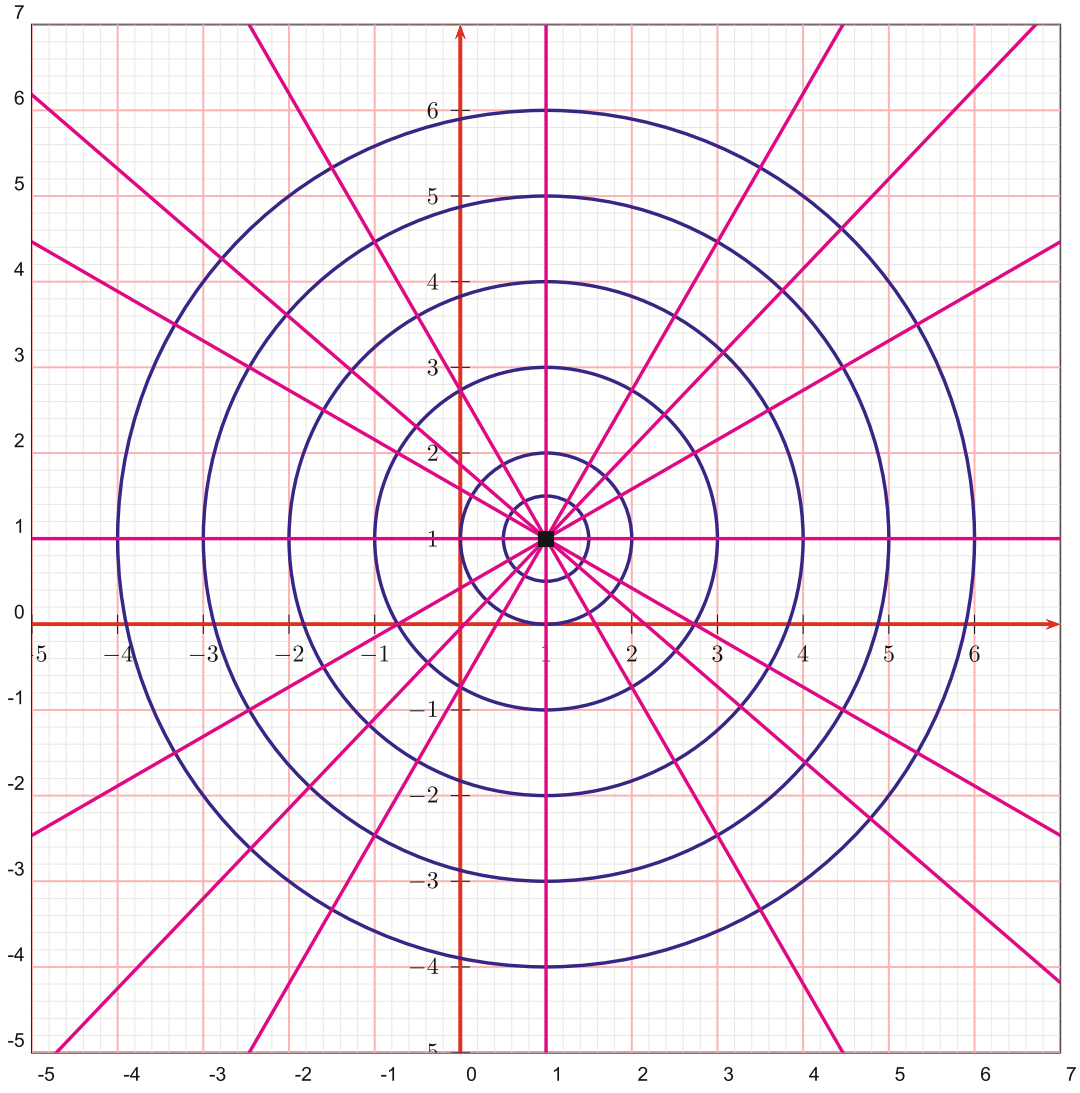
which leads to

$$2uv\overrightarrow{m_1}\ \ \overrightarrow{m_2}=1$$

As $\overrightarrow{m_1}\blacksquare\,\overrightarrow{m_2}=-8$, the relation

$$v=-\frac{1}{16u}$$

is obtained and the representation of the second pencil is



Pencils of Spheres in the Minkowski-Lorentz Spaces, Fig. 7 Two pencils of orthogonal circles. The lines are obtained with $t \in \left\{0, \frac{\pi}{6}, \frac{\pi}{4}, \frac{\pi}{3}, \frac{\pi}{2}, \frac{2\pi}{3}, \frac{3\pi}{4}, \frac{5\pi}{6}\right\}$ whereas the circles with the center Ω_0 are obtained with $u \in \left\{2, 1, \frac{1}{2}, \frac{1}{3}, \frac{1}{4}, \frac{1}{5}\right\}$

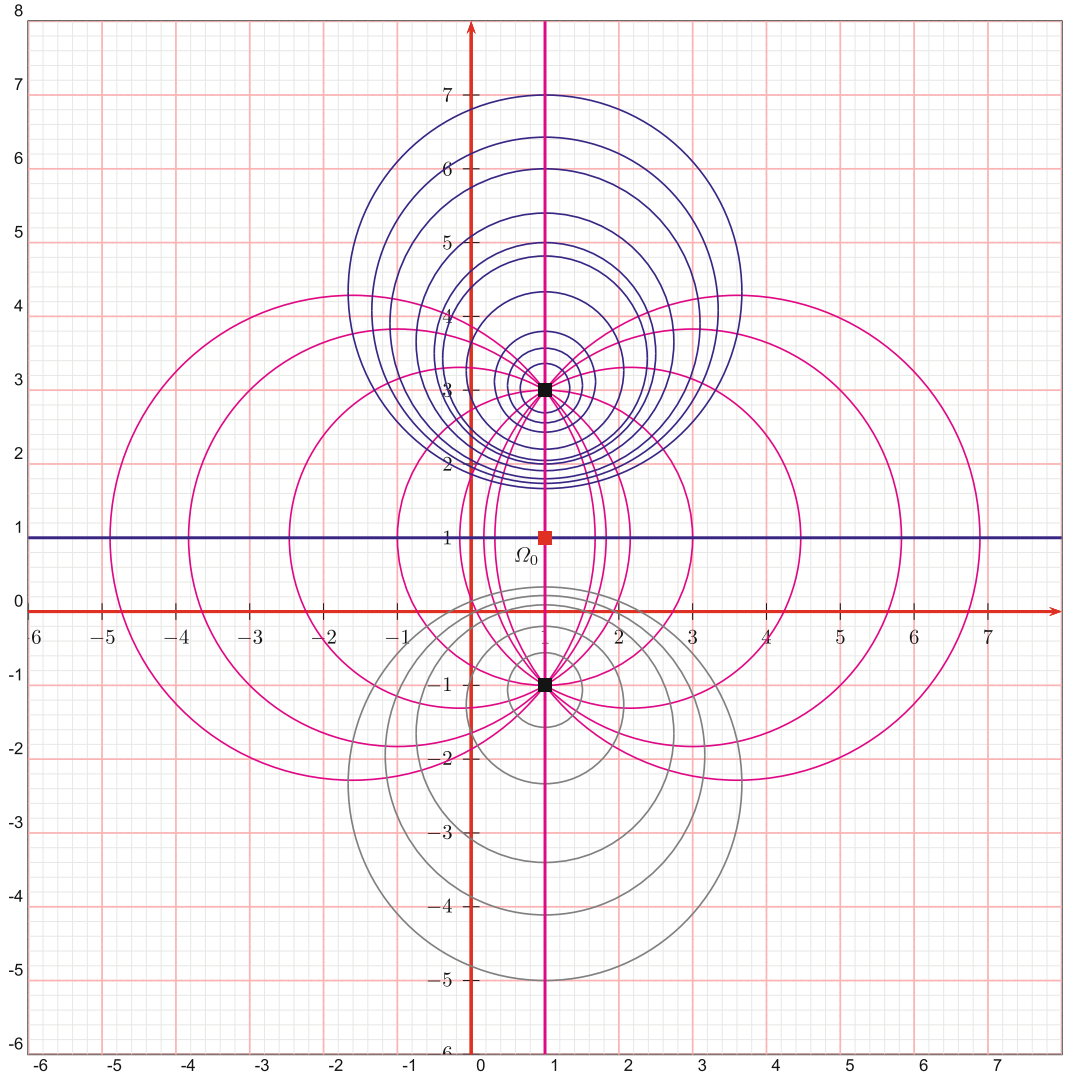
$$\begin{aligned}\vec{\sigma}\,(t) &= u\,\overrightarrow{m_1} - \frac{1}{16\,u}\,\overrightarrow{m_2} \\ &= \frac{16\cdot u^2-1}{16\cdot u}\,\overrightarrow{e_o} + \frac{16\cdot u^2-1}{16\cdot u}\,\overrightarrow{e_1} \\ &\quad + \frac{48\cdot u^2+1}{16\cdot u}\,\overrightarrow{e_2} + \frac{80\cdot u^2-1}{16\cdot u}\,\overrightarrow{e_\infty}\end{aligned}$$

which leads to a pencil of concentric circles of center $\Omega_u\left(1, \frac{48\,u^2+1}{16\,u^2-1}\right)$ and of radius $r_u = \frac{16\,u}{16\,u^2-1}$ where $u \in \mathbb{R} - \left\{-\frac{1}{4}, \frac{1}{4}\right\}$, see Fig. 8.

If $u = \frac{\varepsilon}{4}$ with $\varepsilon \in \{-1, 1\}$, $\vec{\sigma}\left(\frac{\varepsilon}{4}\right)$ is computed as follow

$$\begin{aligned}\vec{\sigma}\left(\frac{\varepsilon}{4}\right) &= \frac{\varepsilon}{4}\,\overrightarrow{m_1} - \frac{\varepsilon}{4}\,\overrightarrow{m_2} = \frac{\varepsilon}{4}\left(\overrightarrow{m_1} - \overrightarrow{m_2}\right) \\ &= \varepsilon\,\overrightarrow{e_2} + \varepsilon\,\overrightarrow{e_\infty}\end{aligned}$$

which represents the line defined by the point Ω_0 and the normal vector $\overrightarrow{e_2}$, see the blue line in Fig. 8.



Pencils of Spheres in the Minkowski-Lorentz Spaces, Fig. 8 Two pencils of orthogonal circles. The circles of the pencil $\mathcal{P}_t$ are obtained with $|\ t\ | \in \left\{0, \frac{\pi}{6}, \frac{\pi}{4}, \frac{7\pi}{24}, \frac{\pi}{2}\right\}$. The blue circles of the Poncelet pencil are obtained with $u \in \left\{\frac{1}{2}, \frac{7}{12}, \frac{13}{24}, \frac{2}{3}, \frac{3}{4}, \frac{4}{5}, 1, \frac{3}{2}, 2, 3\right\}$ whereas the gray circles of the Poncelet pencil are obtained with $u \in \left\{\frac{1}{32}, \frac{1}{16}, \frac{3}{32}, \frac{7}{64}, \frac{1}{8}\right\}$

One can note that the base points M_1 and M_2, in black in Fig. 8, of the first pencil $\mathcal{P}_t$ are the limit points of the Poncelet pencil.

Example with a Pencil of Tangent Circles in $\mathcal{E}_2$

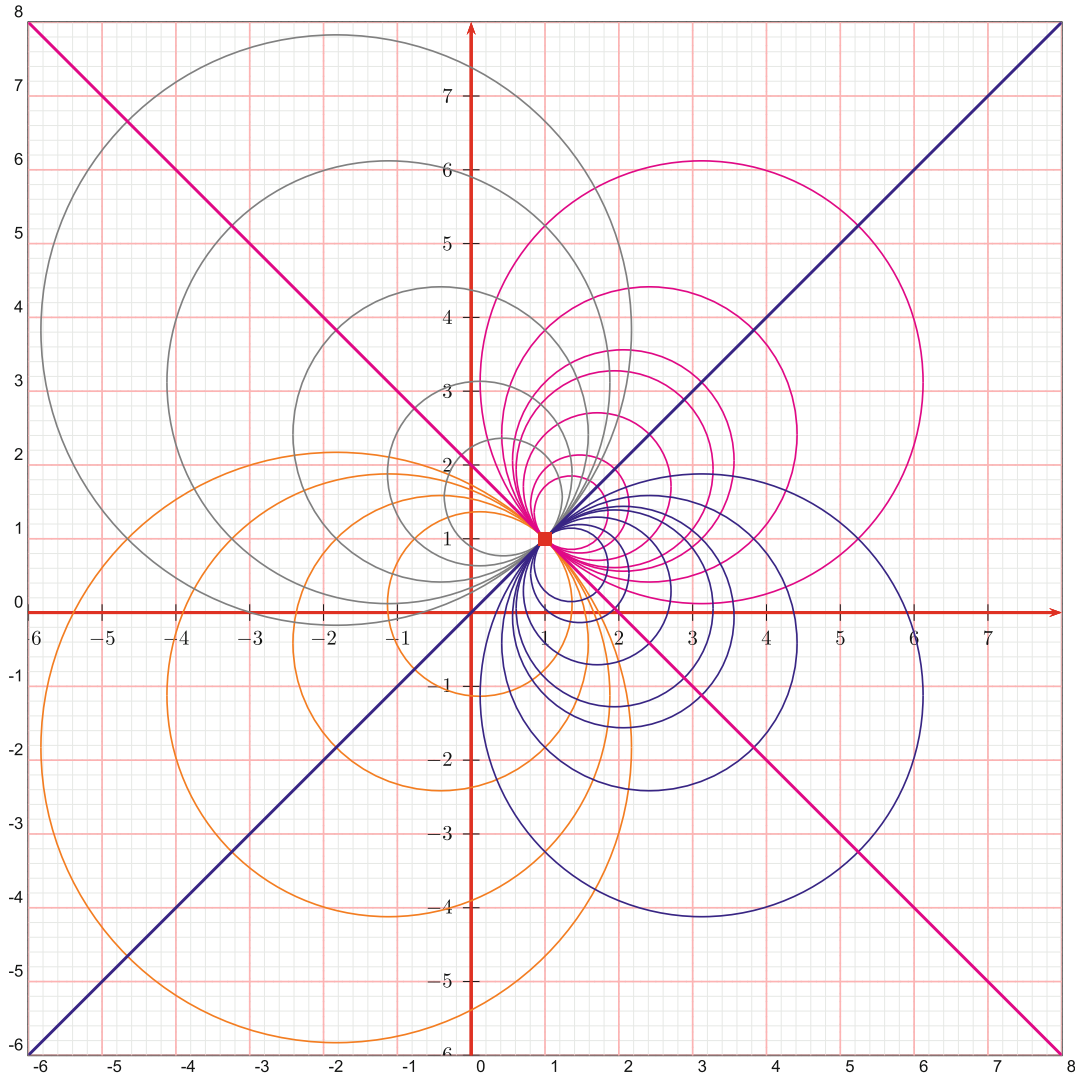
Let $\mathcal{P}_t$ be the pencil of circles tangent at the points $\Omega_0\ (1,\ 1)$ and centered on the line defined by Ω_0 and $\vec{u}\,(1,1)$. The representation of the line generated by Ω_0 and $\overrightarrow{u_0}\left(\frac{\sqrt{2}}{2}, \frac{\sqrt{2}}{2}\right)$ in $\mathrm{L}_{3,1}$ is

$$\overrightarrow{\pi_0}\left(0, \frac{\sqrt{2}}{2}, \frac{\sqrt{2}}{2}, \sqrt{2}\right)$$

and the pencil is represented by

$$\overrightarrow{\sigma_0}\,(t) = \overrightarrow{\pi_0} + t\,\overrightarrow{o_0}$$

where $\overrightarrow{o_0}\,(1,1,1,1)$ is the representation of the point Ω_0. The center (resp. radius) of the circle of the pencil is $\Omega_0(t)\left(\frac{2t+\sqrt{2}}{2t}, \frac{2t+\sqrt{2}}{2t}\right)$ (resp. $\rho_0(t) = \frac{1}{t}$).



Pencils of Spheres in the Minkowski-Lorentz Spaces, Fig. 9 Two pencils of orthogonal circles. The magenta (resp. orange) circles of the pencil $\mathcal{P}_t$ are obtained with $t \in \left\{\frac{1}{3}, \frac{1}{2}, \frac{2}{3}, \frac{3}{4}, 1, \frac{3}{2}, 2\right\}$ (resp. $t \in \left\{-\frac{1}{4}, -\frac{1}{3}, -\frac{1}{2}, -\frac{4}{5}\right\}$). The blue (resp. gray) circles of the second pencil are obtained with $u \in \left\{\frac{1}{3}, \frac{1}{2}, \frac{2}{3}, \frac{3}{4}, 1, \frac{3}{2}, 2\right\}$ (resp. $u \in \left\{-\frac{1}{4}, -\frac{1}{3}, -\frac{1}{2}, -\frac{4}{5} - \frac{5}{4}\right\}$)

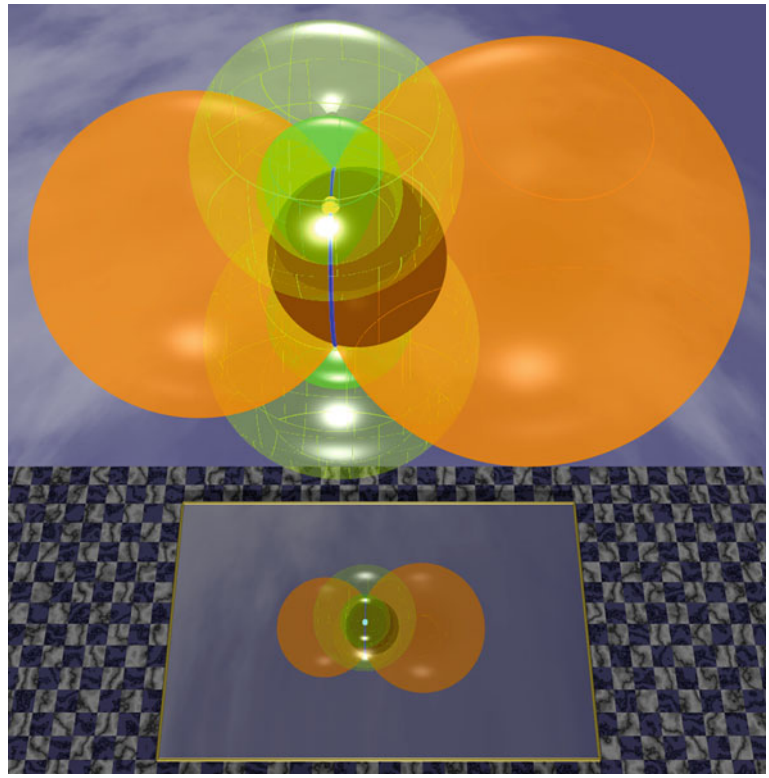
The pencil $\mathcal{P}_t$ is represented by the 2-plane defined by the point O_4, the space-like vector $\overrightarrow{\pi_0}$ and the light-like vector $\overrightarrow{o_0}$ which is orthogonal to itself. The second pencil is defined by a light-like 2-plane generated by the point O_4, a space-like vector $\overrightarrow{\pi_1}$ and the light-like vector $\overrightarrow{o_0}$. To simplify the computation, the space-like vector $\overrightarrow{\pi_1}(0, x_1, x_2, x_\infty)$ represents a plane and verifies the following conditions:

$$\begin{cases} \overrightarrow{\pi_0} \blacksquare \overrightarrow{\pi_1} &= \frac{\sqrt{2}}{2}x_1 + \frac{\sqrt{2}}{2}x_2 &= 0 \\ \overrightarrow{o_0} \blacksquare \overrightarrow{\pi_1} &= x_1 + x_2 - x_\infty &= 0 \\ \overrightarrow{\pi_1}^2 &= x_1^2 + x_2^2 &= 1 \end{cases}$$

and one solution is

$$\overrightarrow{\pi_1}\left(0, \frac{\sqrt{2}}{2}, -\frac{\sqrt{2}}{2}, 0\right)$$

P



Pencils of Spheres in the Minkowski-Lorentz Spaces, Fig. 10 Two pencils of orthogonal spheres. The color of the spheres of the pencil $\mathcal{P}_t$ is orange and the color of the circle is blue. The color of the spheres of the Poncelet pencil is green, and the colors of the limit point are yellow and cyan

which is the representation of the line defined by the point Ω_0 and the normal vector $\overrightarrow{u_1}\left(\frac{\sqrt{2}}{2}, -\frac{\sqrt{2}}{2}\right)$. One can note that the second solution is $-\overrightarrow{\pi_1}$. So, the pencil is represented by

$$\overrightarrow{\sigma_1}(u) = \overrightarrow{\pi_1} + u\,\overrightarrow{o_0}$$

and the center (resp. radius) of the circle of the pencil is $\Omega_1(u)\left(\frac{2u+\sqrt{2}}{2u}, \frac{2u-\sqrt{2}}{2u}\right)$ (resp. $\rho_1(u) = \frac{1}{u}$), see Fig. 9.

One can note that

$$\begin{aligned}\overrightarrow{\sigma_0}(t)_{\blacksquare}\,\overrightarrow{\sigma_1}(u) &= \left(\overrightarrow{\pi_0} + t\,\overrightarrow{o_0}\right)_{\blacksquare}\left(\overrightarrow{\pi_1} + u\,\overrightarrow{o_0}\right)\\ &= \underbrace{\overrightarrow{\pi_0}_{\blacksquare}\,\overrightarrow{\pi_1}}_{0} + u\underbrace{\overrightarrow{\pi_0}_{\blacksquare}\,\overrightarrow{o_0}}_{0} + t\underbrace{\overrightarrow{o_0}_{\blacksquare}\,\overrightarrow{\pi_1}}_{0}\\ &\quad + \underbrace{\overrightarrow{o_0}^2}_{0}\\ &= 0\end{aligned}$$

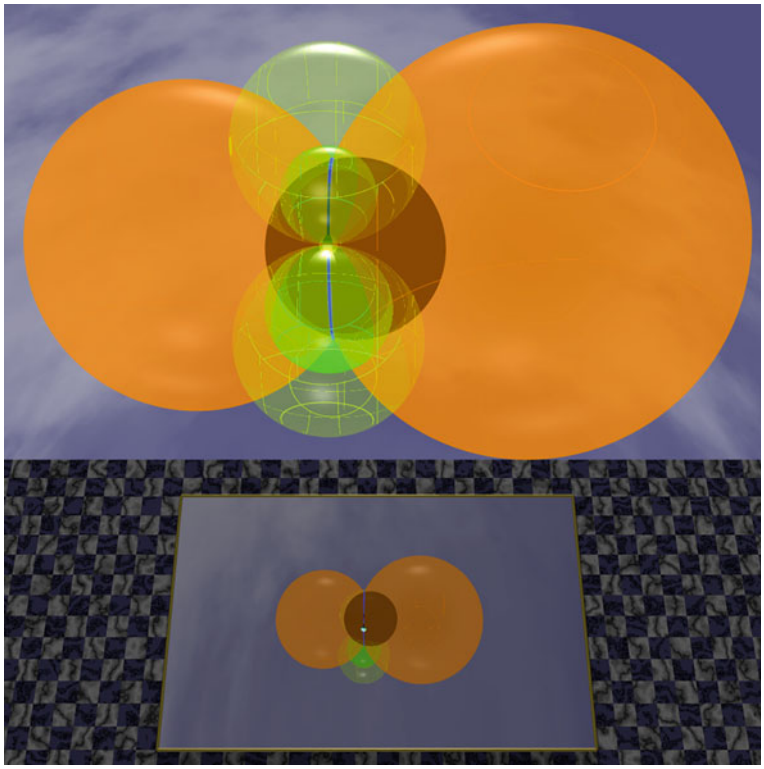
Moreover, the dimension of the vector space generated by $\overrightarrow{\pi_0}$, $\overrightarrow{\pi_1}$ and $\overrightarrow{o_0}$ is $3 < 4$. A light-like direction misses. The vector $\overrightarrow{e_\infty}$ is orthogonal to the representation of any lines of $\mathcal{E}_2$, so, a basis of $\overrightarrow{L_{3,1}}$ is $\left(\overrightarrow{\pi_0}, \overrightarrow{\pi_1}, \overrightarrow{o_0}, \overrightarrow{e_\infty}\right)$.

Example with a Pencil of Spheres which Base Circle in $\mathcal{E}_3$

In this section, let $\mathcal{P}_t$ be the pencil of spheres obtained by the transformation of circles in section "Example with a Pencil of Circles Which Base Points in ε_2" into spheres having the same radii. Using the type of the line, Table 5, one can choose the kind of the second pencil.

Poncelet Pencil with Spheres Orthogonal to the Spheres of $\mathcal{P}_t$

Using the space-like line Δ defined by the point O_3 and the vector $\overrightarrow{e_3}$, the circles of the second pencil in section "Example with a Pencil of Circles Which Base Points in ε_2" are transformed into spheres having the same radii, see Fig. 10.



Pencils of Spheres in the Minkowski-Lorentz Spaces, Fig. 11 Two pencils of orthogonal spheres. The color of the spheres of the pencil $\mathcal{P}_t$ is orange and the color of the circle is blue. The color of the spheres of the pencil of the tangent spheres is green. The color of the point of tangency is yellow whereas the color of the point which generates the fifth dimension is cyan (see the mirror)

Pencil of Tangent Spheres Orthogonal to the Spheres of $\mathcal{P}_t$

To obtain a light-like 2-plane, the type of the line Δ is light-like defined by the light-like vector

$$\vec{\nabla}(1, x_1, x_2, x_3, x_\infty)$$

which verifies

$$\begin{cases} \vec{\sigma_0} \blacksquare \vec{\nabla} = 0 \\ \vec{\pi_0} \blacksquare \vec{\nabla} = 0 \\ \vec{\nabla}^2 = 0 \end{cases} \tag{29}$$

with $\vec{\sigma_0}\left(\frac{1}{2}, \frac{1}{2}, \frac{1}{2}, 0, \frac{-1}{2}\right)$ (resp. $\vec{\pi_0}(0, 1, 0, 0, 1)$). Let x_3 be the degree of freedom. The system of Formula (29) is equivalent to

$$\begin{cases} x_1 + x_2 - x_\infty + 1 = 0 \\ x_1 - 1 = 0 \\ x_1^2 + x_2^2 + x_3^2 - 2x_\infty = 0 \end{cases} \tag{30}$$

which leads to

$$\begin{cases} x_2 = x_\infty - 2 \\ x_1 = 1 \\ x_\infty^2 - 6x_\infty + 5 + x_3^2 = 0 \end{cases} \tag{31}$$

The third equation have real solutions if

$$16 - 4x_3^2 \geq 0$$

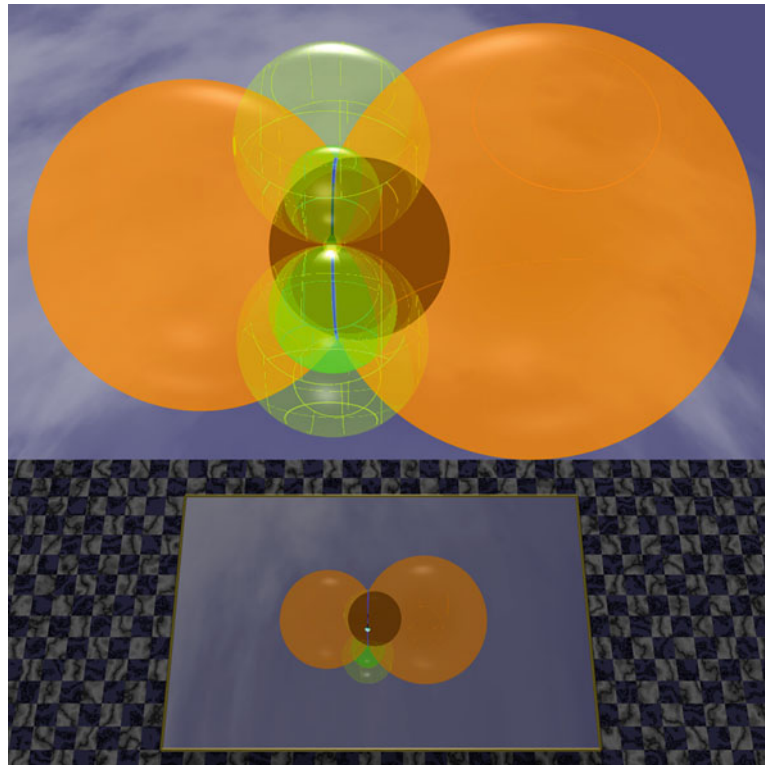
which is equivalent to

$$| x_3 | < 2$$

and the light-like vector is

$$\vec{\nabla_\varepsilon}\left(1, 1, 1 + \varepsilon\sqrt{4 - x_3^2}, x_3, 3 + \varepsilon\sqrt{4 - x_3^2}\right)$$

with $\varepsilon \in \{-1; 1\}$ which represents the point $M_l\left(1, 1 + \varepsilon\sqrt{4 - x_3^2}, x_3\right)$. If $\vec{\nabla_{-\varepsilon}}$ is the direction



Pencils of Spheres in the Minkowski-Lorentz Spaces, Fig. 12 Two pencils of orthogonal spheres. The color of the spheres of the pencil $\mathcal{P}_t$ is orange and the color of the circle is blue. The color of the spheres of the pencil of the tangent spheres is green. The color of the point of tangency is yellow whereas the color of the point which generates the fifth dimension is cyan (see the mirror)

of the line Δ, then $\overrightarrow{\nabla_\varepsilon}$ represents the point of tangency of the second pencil. The 2-plane $\overrightarrow{\pi_1}$ representing the second pencil verifies

$$\begin{cases} \overrightarrow{\sigma_0} \blacksquare \overrightarrow{\pi_1} = 0 \\ \overrightarrow{\pi_0} \blacksquare \overrightarrow{\pi_1} = 0 \\ \overrightarrow{\nabla_1} \blacksquare \overrightarrow{\pi_1} = 0 \\ \overrightarrow{\pi_1}^2 = 1 \end{cases} \tag{32}$$

which leads to

$$\overrightarrow{\pi_1}\left(0, 0, \frac{x_3}{2}, -\frac{\sqrt{4 - {x_3}^2}}{2}, \frac{x_3}{2}\right)$$

and the plane $\overrightarrow{\pi_1}$ represents the plane of $\mathcal{E}_3$ defined by the point Ω_0 and the normal vector $\overrightarrow{v_1}\left(0, \frac{x_3}{2}, -\frac{\sqrt{4-x_3^2}}{2}\right)$. Figure 11 shows an example with $x_3 = -1$.

Pencil of Spheres with Base Circle Orthogonal to the Spheres of $\mathcal{P}_t$

To obtain a space-like 2-plane, the type of the line Δ is time-like defined by the light-like vector

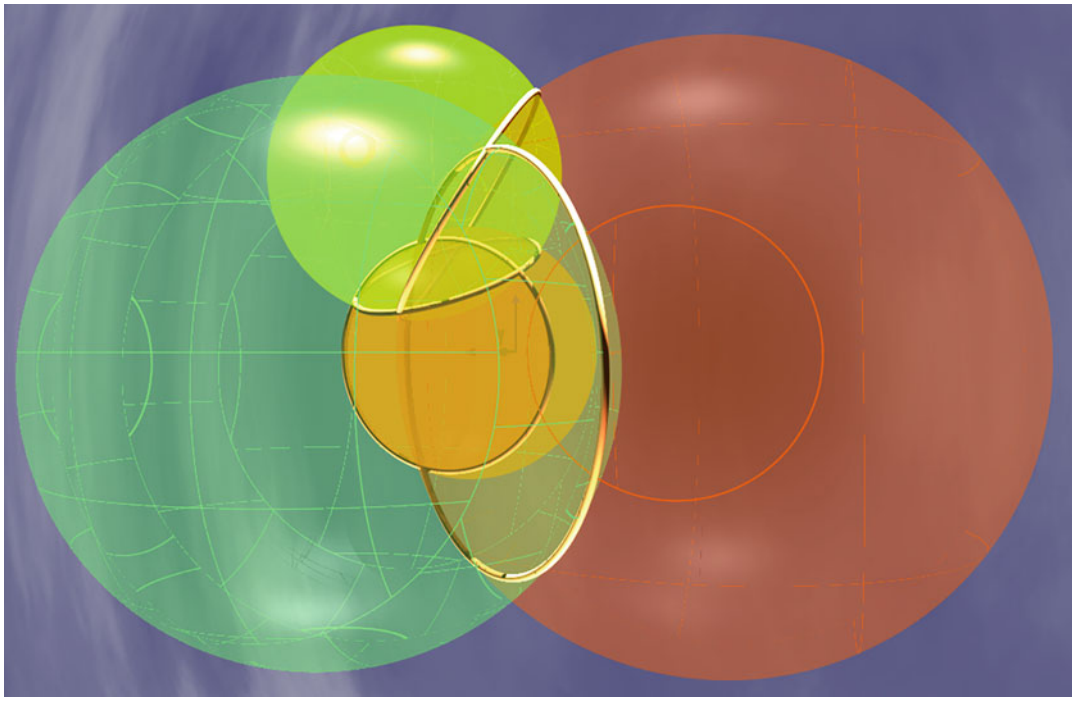
$$\vec{\nabla}\,(x_o, x_1, x_2, x_3, x_\infty)$$

which verifies

$$\begin{cases} \overrightarrow{\sigma_0} \blacksquare \vec{\nabla} = 0 \\ \overrightarrow{\pi_0} \blacksquare \vec{\nabla} = 0 \\ \vec{\nabla}^2 < 0 \end{cases} \tag{33}$$

with $\overrightarrow{\sigma_0}\left(\frac{1}{2}, \frac{1}{2}, \frac{1}{2}, 0, \frac{1}{2}\right)$ (resp. $\overrightarrow{\pi_0}\,(0, 1, 0, 0, 1)$). The system of Formula (29) is equivalent to

$$\begin{cases} x_o + x_1 + x_2 = x_\infty = 0 \\ x_1 - 1 = 0 \\ x_1^2 + x_2^2 + x_3^2 - 2x_o x_\infty = 0 \end{cases} \tag{34}$$



Pencils of Spheres in the Minkowski-Lorentz Spaces, Fig. 13 Two spheres of each pencil of orthogonal spheres, Fig. 12 and the circles of intersection

which leads to

$$\begin{cases} x_\infty = 2x_o + x_2 \\ x_1 = x_o \\ x_2^2 + x_3^2 - 3x_o^2 - 2x_o x_2 < 0 \end{cases} \tag{35}$$

$x_o = x_1 = 1$, $x_2 = 2$, and $x_3 = 1$ which lead to $x_\infty = 4$ and $\overrightarrow{\nabla}^2 = -2$. To simplify the computations, the 2-plane representing the second pencil is generated by $\overrightarrow{\pi_1}\,(0, y_1, y_2, y_3, y_\infty)$ (resp. $\overrightarrow{\sigma_1}\,(z_o, z_1, z_2, z_3, z_\infty)$) which represents a plane (resp. sphere) of $\mathcal{E}_3$. The vector $\overrightarrow{\pi_1}$ verifies

$$\begin{cases} \overrightarrow{\sigma_0} \blacksquare \overrightarrow{\pi_1} = 0 \\ \overrightarrow{\pi_0} \blacksquare \overrightarrow{\pi_1} = 0 \\ \overrightarrow{\nabla_1} \blacksquare \overrightarrow{\pi_1} = 0 \\ \overrightarrow{\pi_1}^2 = 1 \end{cases} \tag{36}$$

which leads to

$$\overrightarrow{\pi_1}\left(0, 0, \frac{\sqrt{2}}{2}, -\frac{\sqrt{2}}{2}, \frac{\sqrt{2}}{2}\right)$$

or $-\overrightarrow{\pi_1}$. The plane $\overrightarrow{\pi_1}$ represents the plane of $\mathcal{E}_3$ defined by the point Ω_0 and the normal vector $\overrightarrow{v_1}\left(0, \frac{\sqrt{2}}{2}, -\frac{\sqrt{2}}{2}\right)$. The vector $\overrightarrow{\sigma_1}$ verifies

$$\begin{cases} \overrightarrow{\sigma_0} \blacksquare \overrightarrow{\sigma_1} = 0 \\ \overrightarrow{\pi_0} \blacksquare \overrightarrow{\sigma_1} = 0 \\ \overrightarrow{\pi_1} \blacksquare \overrightarrow{\sigma_1} = 0 \\ \overrightarrow{\nabla_1} \blacksquare \overrightarrow{\sigma_1} = 0 \\ \overrightarrow{\sigma_1}^2 = 1 \end{cases} \tag{37}$$

which leads to

$$\overrightarrow{\sigma_1}\left(\frac{1}{2}, \frac{1}{2}, \frac{3}{2}, 1, \frac{5}{2}\right)$$

or $-\overrightarrow{\sigma_1}$. The vector $\overrightarrow{\sigma_1}$ represents the sphere of $\mathcal{E}_3$ of center Ω_1 (1, 3, 2) and of radius $\rho_1 = 2$. The representation of the second pencil in $L_{4,1}$ is

P

$$\vec{\tau}(t) = \cos(t)\vec{\sigma_1} + \sin(t)\vec{\pi_1}$$

Figure 12 shows some spheres of these pencils.

Figure 13 shows two spheres of these pencils and the circles.

Conclusion

This entry presents an application of the Minkowski-Lorentz space and its interest for Computer Graphics: the representation and computations of pencils of circles or spheres. These pencils are represented by unit circles, that is, the intersection between the unit hypersphere Λ^{n+1} and a 2-plane passing through the origin. From a Euclidean point of view, these unit circles look like ellipse, hyperbola, or the union of two straight lines. So, these pencils can be represented using rational quadratic Bézier curves and mass points. Moreover, from a pencil of spheres, this kind of representation eases the computation of an other pencil of orthogonal spheres (a sphere of a pencil is orthogonal to the spheres of the other pencil): the construction of a 2-plane passing through the origin and orthogonal to the previous 2-plane leads to the second pencil.

In the future, from a pencil of spheres in the 3D usual Euclidean space, a one-parameter family of Dupin cyclides will be computed using the Minkowski-Lorentz space.

Perceptual Illusions and Distortions in Virtual Reality

Niels Christian Nilsson
Aalborg University Copenhagen, Copenhagen, Denmark

Synonyms

Distance misperception; Self-motion misperception; Vection; Virtual body-ownership

Definitions

Virtual Reality (VR) enables users to act and perceive as they do during everyday interactions with the word. As a consequence, VR may deliberately or inadvertently elicit a range of perceptual illusions and distortions on behalf of immersed users.

Introduction

From an early age, people become experts at deciphering the continuous stream of stimuli registered by various sensory systems in response to the perceiver's own actions and events in the environment. However, even though the senses provide reasonably reliable information, perception is imperfect, leaving the perceiver vulnerable to illusions, i.e., instances of erroneous or misinterpreted perceptions of sensory information (Stevenson 2010).

A defining feature of Virtual Reality (VR) systems is that they support natural perception and actions by means of high fidelity tracking and displays. That is, VR systems support a sensorimotor loop similar to that of the real world and enable users to interact and perceive as they would during unmediated experiences. Thus, VR systems may inadvertently or deliberately elicit a range of perceptual illusions and distortions. Based on our previous writings on the topic (Serafin et al. 2014), this entry details a selection of well-documented perceptual illusions and distortions known to occur during exposure to VR and discusses how they can be leveraged in order to provide more compelling experiences of virtual environments (VEs).

Illusions of Place and Plausibility

What separates VR from traditional audiovisual media is arguably that it elicits an unprecedented degree of presence on behalf of the user. A number of different conflicting and complimentary theories of presence have been proposed (e.g., Lombard and Ditton 1997; Riva et al. 2011; Waterworth and Waterworth 2001). However, the view of presence advocated by Slater and colleagues is particularly relevant to the current discussion because it explicitly focuses on presence as a response to VR (e.g., Sanchez-Vives and Slater 2005; Slater 2009; Slater et al. 2010a). Generally, the degree of presence is viewed as the extent to which the user responds to realistically to the VE. If the VE elicits a high degree of presence then users will respond more or less exactly as they would when exposed to an equivalent scenario in the real world. This implies that the presence response occurs on multiple levels ranging from unconscious and automatic physiological and behavioral responses to higher level processes involving deliberation and thoughts. Thus, even though presence is subjectively felt, the presence response cannot be reduced to a subjective experience (Sanchez-Vives and Slater 2005). Nevertheless, Slater et al. (2010a) have argued that the presence response happens as a function of two illusions: the *place illusion* (PI) and the *plausibility illusion* (Psi).

PI can be described as to the illusion of "being there" in the VE. This illusion occurs in response to the VR system supporting the normal sensorimotor contingencies of the user (i.e., the normal actions the user can perform in order to perceive and affect the VE). For example, if the user turns her head or kneels down then displayed image and sound should reflect this change in perspective, and if she reaches out and grasps an object then this action should cause that object to move (Slater 2009). Specifically, Slater et al. (2010a) describe that when "a person perceives by carrying out actions that result in changes in (multisensory) perception much as in physical reality, then the simplest hypothesis for the brain to adopt is that what is being perceived is actually there" (p. 3). The concept technological *immersion* is sometimes associated with systems that support normal sensorimotor contingencies. That is, the degree of immersion is defined as the range of normal sensorimotor contingencies supported by the system.

Psi, the second illusion introduced by Slater (2009), refers to the illusion that the events happening virtually are indeed happening. Rovira et al. (2009) argue that Psi is a more difficult illusion to elicit than PI, and it requires that the VE satisfies at least three criteria: (1) The VE should be *correlational*. The user's actions produce correlated reactions within the VE (e.g., a virtual character might avoid eye-contact and step aside if the user stares and exhibit aggressive body language). (2) The VE should be *self-referential*. The VE responds directly to the

user's presence even when the user does not perform an instigating action (e.g., a virtual character might react to the presence of the user without the user initially approaching or addressing said character). (3) The VE should be *credible*. The VE conform to the user's knowledge and expectations accrued through a lifetime of nonmediated interactions. Notably, Skarbez et al. (2017) have introduced the concept *coherence* as a (possibly) objective characteristic of the VE that gives rise to Psi. Importantly, coherence is viewed as a superset of realism, implying that in order to be coherent the VE need not strictly adhere to real-world laws and norms. Instead, coherence depends on the degree to which the user finds the virtual experience to possess internal logic and behavioral consistency. Thus, a virtual fantasy world may be coherent as long as fantastic events and behaviors are consistent.

Finally, Slater (2009) has described the virtual body as "a focal point where PI and Psi are fused" (p. 3554). The virtual body will be the topic of the following section.

Body Ownership Illusions

Individuals make sense of incoming sensory stimuli based on tacit expectations as to how these stimuli relate to their own actions and events in the environment. Thus, when reaching for an object, you expect to see your extended arm, and when directing your gaze downward, you expect to see your own body. However, when immersed in a VE, you cannot take for granted that such actions will bring your body into view. If the user is wearing a head-mount display (HMD), her real body will be occluded and tracking of the various body-parts is necessary in order to map a virtual representation onto the real body. When done successfully this may cause the user to experience an illusion of virtual body ownership, i.e., the experience that an artificial body is in fact one's own physical body (Maselli and Slater 2013).

The illusion of ownership of artificial body-parts was first demonstrated without the use of VR technology. Specifically, Botvinick and Cohen (1998) documented the so-called *rubber hand illusion* where subjects experienced a sense of ownership over a rubber hand placed in front of them when tactile stimuli was synchronously applied to their real hand and the rubber hand. Ten years after the rubber hand illusion was first described, Slater et al. (2008) showed that it can be replicated in VR. Work by Maselli and Slater (2013) explored the perceptual underpinnings for full body ownership illusions in VR. Their work among other things revealed that (1) a first person perspective is central to the virtual body-ownership. (2) Visio-proprioceptive cues can elicit body-ownership illusions when users are exposed to a virtual body that spatially overlaps with the real body from a first person perspective. (3) When the spatial overlap or the realism of virtual body is limited, then multisensory or sensorimotor cues are necessary in order to produce the body-ownership illusion.

Interestingly, virtual body-ownership illusions can occur even when the virtual body differs from the users own body. For example, the illusion can occur when the virtual and real bodies differ in regard to size (Normand et al. 2011), gender (Slater et al. 2010b), age (Banakou et al. 2013), and race (Maister et al. 2013). Moreover, ownership illusions may even occur when the subject is exposed to nonhuman virtual bodies (e.g., humanoid robots and cartoon-like avatars Lugrin et al. 2015) and when these bodies have additional limbs (e.g., a virtual tail Steptoe et al. 2013). Work exploring the effects on virtual body-ownership suggests that ownership of a foreign body affects subject' perceptions, attitudes, and actions. For example, implicit racial bias may be reduced when subjects have been exposed to a virtual body with a different skin color (Peck et al. 2013) and adult subjects embodying a child's body may be more likely to overestimate the size of virtual objects (Banakou et al. 2013).

Distortions of Virtual Distances

Perceptual distortions of virtual spaces and objects are not only phenomena that occur when

users embody a foreign avatar, such as an adult inhabiting the virtual body of a child. One of the most well-documented perceptual distortions of virtual spaces relate to the perception of egocentric distances. Users tend to underestimate virtual distances. That is, individuals tend to find the distance between their own position and virtual objects shorter than it really is. Based on a review of the literature, Renner et al. (2013) broadly divide the factors influencing virtual distance misperception into four categories: technical factors, compositional factors, human factors, and measurement methods.

Technical factors do as the name implies relate to the properties of the software and hardware used to render and display the VE. Specifically, Renner et al. (2013) highlight a number of properties of HMDs that may account for some of the underestimation. For example, some of the underestimation may be attributed to the combination of a restricted field of view (FOV), the mass and moment of inertia of HMDs, along with the feeling of wearing the HMDs. Moreover, the accommodation-convergence conflict may introduce underestimations, but it is unclear whether graphics quality is of influence.

Compositional factors relate to the features of the VE presented to the user. The review by Renner et al. (2013) suggests that the literature is fairly consistent in regard to the effects of pictorial depth cues on distance perception. Particularly, the authors describe that distance estimates may be positively influenced by the addition of complexity to the VE. Moreover, the use of a correct avatar may also improve distance estimates.

The third category, *human factors*, relate to the users' psychological characteristics. Renner et al. (2013) describe that distance estimation does not appear to be influenced by gender or variations in age among adults. The ability to estimate virtual distances may be improved by providing individuals with feedback on their performance. However, the resulting adaptation to virtual distances may necessarily reduce transfer of skills from VR to real life.

In regard to the final group of factors, *measurement methods*, a number of different measures have been proposed. All measures quite consistently suggest that individuals underestimate egocentric distances in VR. However, different measures are a likely to produce difference estimates of the underestimation. Renner et al. (2013) describe that blind throwing and blind walking estimates yield comparable results; blind reaching estimates may offer higher accuracy and consistency than verbal estimates; timed imagined walking and blind walking produce similar estimates; and blind walking estimates are generally more accurate than estimates resulting from triangulated blind walking and indirect blind walking.

Finally, Renner et al. (2013) recommend that in order to facilitate the best possible distance estimation in VEs, developers should "provide binocular disparity, use high quality of graphics, carefully adjust the virtual camera settings, display a rich virtual environment containing a regularly structured ground texture, and enhance the user's sense of presence" (p. 23).

Self-motion Illusions and Distortions

It is not just the perception of virtual distances that are prone to misperceptions. Virtual walking accomplished using a treadmill may also be accompanied by perceptual distortions. If a user were walking on a linear treadmill while wearing a HMD, then one would expect that the visual speed presented to the user should match the speed of the treadmill's belt. However, it has been demonstrated that the walker is likely to perceive matched visual speeds as too slow (Banton et al. 2005; Kassler et al. 2010; Nilsson et al. 2016; Powell et al. 2011). Notably, a similar perceptual distortion appears to be present when users are relying on walking-in-place techniques for virtual travel (Nilsson et al. 2016). While the phenomenon and its causes have yet to be fully understood, previous user studies have yielded the following insights: (1) The distortion may be eliminated if walkers direct their gaze downwards or to the side (Banton et al. 2005). (2) Image jitter does not appear to be responsible for the distortion (Banton et al. 2005). (3) No effect of increased

HMD weight or varying peripheral occlusion have been found (Nilsson et al. 2015a, b). (4) The degree of underestimation appears to be inversely proportional to the size of the display FOV and the geometric FOV (Nilsson et al. 2014a; 2015a). (5) The degree of identified underestimation may vary depending on study methods (Nilsson et al. 2015a). (6) High step frequencies may lead to a larger degree of underestimation, but the evidence is somewhat equivocal with respect to this effect (Nilsson et al. 2014b; Durgin et al. 2007; Kassler et al. 2010); (7) Finally, the degree of underestimation may vary slightly depending on whether the user is walking on a treadmill or walking in place (Nilsson et al. 2016).

Turning to the topic of illusory self-motion, one does not need to be immersed in a VE in order to experience visually induced self-motion illusions, that is, *vection* (Lowther and Ware 1996). The following scenario is likely to elicit a vection illusion. A passenger is sitting on a stationary train, looking out the window at another train in the adjacent track. When this second departs, the passenger experiences a transient, yet compelling, that she is on board the trains which is moving. This example illustrates how optokinetic stimuli may be open to at least two perceptual interpretations (Brandt et al. 1973). The passenger either (falsely) perceives the surroundings as being stationary, while she is moving or (correctly) perceives herself as being stationary while the second train is moving. Riecke et al. (2005b) describe that vection is influenced both by the properties of the physical stimuli indicative of self-motion (*bottom-op factors*) and by the perceivers' expectations to and interpretation of said stimuli (*top-down factors*). Notably, visual stimuli is not a prerequisite for vection, as self-motion illusions can occur during exposed to auditory, vibrotactile, and biomechanical stimulation (Nordahl et al. 2012; Riecke et al. 2005a; Riecke and Schulte-Pelkum 2013; Väljamäe 2009). The bottom-up factors affecting visually induced self-motion illusions include the stimuli's speed of movement, the perceived depth structure of the visual stimuli, and the area of the visual field occupied by the stimuli (Riecke et al. 2005a). Three of the three primary auditory cues for discrimination of motion are sound intensity, binaural cues, and the Doppler effect (Väljamäe 2009). Recent work on haptically induced self-motion illusions used a combination of vibrotactile stimulation to the main supporting areas of the feet and a virtual elevator to elicit sensations of upward and downward movements (Nordahl et al. 2012). Because the walls of the virtual elevator were opaque, no visual self-motion cues were presented (i.e., optic flow). Thus, it seems likely that the participants' expectation of vertical movement (a top-down factor) contributed to the illusion. Other examples of top-down factors shown to affect vection include the belief that self-motion is possible (Riecke et al. 2005b, 2008; Wright et al. 2006), and explicitly being asked to attend to either the sensation of self-motion or object motion (Palmisano and Chan 2004).

Leveraging Perceptual Illusions in VR

A defining feature of VR is arguably its ability to elicit both the illusion of "being there" in the VE (the place illusion) and the illusion that the unfolding events are indeed happening (the plausibility illusion). As a consequence, the VR system may cause the user to respond realistically to the VE (a presence response). Bowman and McMahan (2007) have argued that it is precisely this ability to produce experiences greatly resembling "the real thing" that is responsible for the success of many past VR applications. For example, virtual exposure therapy functions because the VE can elicit a elicit a genuine fear response, and military and medical training applications are of value exactly because they can produce a realistic scenario without the presence of any real danger to soldiers or patients. It is arguably also this capacity for providing seemingly real experiences of actual, fictional, and fantastic places that gives VR its appeal with respect to entertainment applications. VR's ability to provide compelling illusions of virtual body-ownership has applications within a range of different domains beyond mere entertainment (e.g., allowing users become a fictional character). The ability to own a body

different from one's own could potentially inspire empathy towards others, and it also seems possible that virtual body-ownership illusions could be leveraged as an intervention or treatment in relation to body image disturbances.

Misperception of virtual distances and virtual walking speeds may pose a considerable problem with respect to some VR applications. For example, veridical spatial perception of distance, scale, and speed may prove to be a fundamental requirement in relation to certain training scenarios or visualization of architecture). Nevertheless, the limitations of human motion perception in VR have also been leveraged in order to compress larger VEs into smaller physical spaces. Most notably, a collection of techniques referred to as *redirected walking* makes it possible to scale, rotate, and curve the user's physical path by subtlety exaggerating or shrinking his real movements (Steinicke et al. 2010). Notably, other perceptual illusions and distortions have also been used to enable redirected walking. For example, Suma et al. (2011) proposed a technique that leverages change blindness illusions in order to move doors and hallways behind the user's and thereby produce overlapping virtual spaces.

Finally, vection is central to the creation of compelling vehicle simulators. Nevertheless, one should be cautious when presenting stationary users with virtual stimuli indicating self-motion. Specifically, this will introduce a visio-vestibular conflict which is believed to cause cybersickness (Davis et al. 2014). Thus, the factors that produce more compelling illusions of self-motion may also cause sickness on behalf of some users.

To conclude, VR systems make it possible to manipulate the senses unlike any traditional audiovisual media. Thus, VR is a near-perfect medium ripe for eliciting perceptual illusions. Moreover, perceptual illusions may serve as a useful tool for solving practical problems (e.g., enabling unconstrained walking in VR), and they may enable developers to provide more compelling experiences (e.g., the illusion of self-motion during vehicular travel). In fact, the presence response which is characteristic of VR is believed to result from the simultaneous occurrence of the place illusion and plausibility illusion.

Role-playing game

Definitions

Role-playing game = a game genre where the player assumes the role of a character in their world.

History of Persona 3

Persona 3 is an interesting role-playing game, to put it simply. The game follows the story of a group of Japanese teens who each have a mysterious power; that being the power to summon a being known as a persona. A persona is a manifestation of a user's personality, which they can use to take down monsters known as Shadows, manifestations of a person's inner thoughts and emotions, usually being negative in nature. They can only use these powers during a secret period of time known as the Dark Hour, which takes place at midnight every night. While playing, the player has to juggle the characters' school lives and their mission to get rid of the Dark Hour at night. Looking at the game through the lens of surprise, the player will come across several moments of surprise.

In Jesse Schell's book *The Art of Game Design: A Book of Lenses*, the Lens of Surprise states that "Surprise is so basic that we can easily forget about it. Use this lens to remind yourself to fill your game with interesting surprises." The Lens of Surprise asks the following questions (Schell, 2019):

1. What will surprise players when they play my game?
2. Does the story in my game have surprises? Do the game rules? Does the artwork? The technology?
3. Do your rules give players ways to surprise each other?
4. Do your rules give players ways to surprise themselves?

Persona 3 has several twists in the story that many players will not see coming, including the death of a major playable character, the betrayal of the group's leader, and a major reveal that the group's efforts were actually having a negative

effect. The fact that the story is so deep and complicated will be a big surprise to anyone new to the series, which was common, as this was the first game in the series to mainstream attention.

For a more in-depth look at the death plot twist, during a botched operation to take out a powerful shadow, one of the characters, Shinjiro, gets trapped by a Shadow. Before anybody can do anything, the shadow kills him, shocking the team and the player, most likely. It comes out of nowhere with nothing hinting toward it. Another example; near the end of the game, it is revealed that in the process of killing all the powerful Shadows, the team unleashed a deity known as Nyx, who will come down at the end of January and bring an end to the world. The characters are informed that they can either have their memories erased of all the events so they can live in ignorant bliss until the fated day comes or they may keep their memories and search for a way to stop Nyx. These events are barely hinted at in the game, and they come as a complete shock for a new player. However, other than the story, there are no real surprises in any other areas of the game, with artwork, rules, and everything else being similar to role-playing games at the time.

With Persona 3 being a single-player game, the only way to experience the shock is by playing it. The battle mechanics can also be surprising to new players. Shadows will have weaknesses and resistances to various types of attacks, so the player might surprise themselves by trying a random attack and finding out it either has no effect or does extra damage against a shadow. The player can also surprise themselves by finding out various skills that fuse together into one, creating significantly more powerful skills.

Overall, while the rules of Persona 3 are, for the most part, unsurprising, along with the technology and artwork, the story has more surprises than most of its contemporaries, with jarring surprises happening frequently, keeping players on their toes.

Ubiquitous games

Definitions

The first academic definition for a pervasive game (Montola 2012) is provided by Schneider and Kortuem (2001), defining a pervasive game as "a LARP [live action role-playing] game that is augmented with computing and communication technology in a way that combines the physical and digital space together." In her pervasive discourse, Nieuwdorp (2007, original italics) highlights the ambiguity of the term "pervasive games" by listing the following meanings which she derived through a literature review (the reader is guided to her work for the sources of the review):

- A game that depends primarily on *pervasive technology and nonstandard input devices*
- An existing game that is *augmented by computers*, resulting in a blend of the real and virtual worlds
- A game that *pervades the real world in an undefined manner, and thus blends with it*

- *A specific setting* of the game world within the real world
- A game that *blurs the boundaries between itself and the real world*, which can influence the concept of the *magic circle*
- A game that is *an overlay* of the real world or where the *world becomes a game board*
- A game with a *persistent presence* in the real world, and thus available to the players at all times
- A game where the *gameplay* interacts with elements of the real world, thus challenging standard gameplay conventions
- A game where there is *mutual interaction among players and elements in the real world*
- A game that blends *with everyday experiences*

Nieuwdorp classifies these meanings into two perspectives: (1) "a *technological* one that focuses on computing technology *as a tool to enable the game to come into being*" (i.e., the first two meanings on the list above) and (2) "a *cultural* one that focuses on *the game itself and, subsequently, on the way the game world can be related to the everyday world*" (the last eight remaining meanings above).

Introduction

Although the origins of ubiquitous computing and pervasive computing differ (Nieuwdorp 2007), they are often used interchangeably (Nieuwdorp 2007; Montola 2012) and both are the basis for pervasive gaming (Nieuwdorp 2007). According to Montola (2005), "a pervasive game is a game that has one or more salient features that expand the contractual magic circle of play spatially, temporally, or socially," i.e., "expand the boundaries of play" (Oppermann 2009).

Pervasive games have been linked to a number of similar genres, such as: ubiquitous games; augmented/mixed reality games; mobile games; alternate reality games; (enhanced) live action role play (E/LARP); affective gaming; virtual reality games; smart toys; location-based or location-aware games; adaptronic games; crossmedia games; augmented tabletop games (Nieuwdorp 2007); and exergames (Stanley et al. 2011).

Staging a Pervasive Game

Ståhl et al. (2007) have identified three temporal phases in staging a pervasive game: "pre-production," "run-time," and "post-production." Because these phases concern games, these phases have also been referred to as "pre-game," "in-game," and "post-game" (Jonsson et al. 2007; Broll et al. 2006). The latter convention is used throughout this entry, reserving run-time to refer to when a game architecture is running and in-game to refer to when the game is running. In the pre-game phase, although resource demanding (Bell 2007), a game can potentially be adapted to each new staging (e.g., adapting to a new staging location (Oppermann 2009), i.e., supporting location adaptability). Adapting the game is done through reconfiguring the architecture and authoring content specific to each staging. Reconfiguration and authoring can continue into the in-game phase, provided it is supported by the architecture. In the post-game phase, an analysis of historic event data can be performed, players debriefed, and informed to the actual flow events (Stenros et al. 2007b). The results of a post-game analysis can inform further game design or stagings.

One of the driving factors why current game engines are ill suited for pervasive games is game mastering. Contrary to many video games, pervasive games do not necessarily run fully automatic. One or more persons, often referred to as *game master(s)* (GMs), can be assigned the responsibility of adjusting the game during its staging; an act which is referred to as *game mastering* (Jonsson and Waern 2008; Oppermann 2009; Montola et al. 2009) or orchestration (Thompson et al. 2003; Flintham et al. 2003a; Broll et al. 2006). A well-known role for a game master is that of a "puppet master": in charge and "pulling strings," all the while staying hidden behind the scenes (Jonsson and Waern 2008). Jonsson and Waern (2008) have argued that pervasive games benefit from being game mastered, e.g., allowing for: content to be actively authored to "fit the activities of the participants," the altering of game events, adjusting of difficulty, providing dynamic gameplay, or the reincorporating of user response back into the game (Jonsson

et al. 2007). Because pervasive games take place in the physical world, another responsibility of the game master is to keep players safe in the highly variable, possibly dangerous conditions of the physical world (Flintham et al. 2003a; Broll et al. 2006). A drawback of game mastering being that it can require a significant amount of human resources (Thompson et al. 2003; Flintham et al. 2003b). Jonsson and Waern (2008) have identified three needed functions, in order to successfully game master: (1) to be able to monitor the game, (2) make decisions about how the game should progress, and (3) have the ability to influence the game state.

Monitoring the Game

Players of pervasive games are mobile and out in the physical world. Two ways to monitor a player are: stationary hardware placed in the physical world (Stenros et al. 2007a; Jonsson and Waern 2008) or by giving players mobile devices to carry, interact, and communicate with (Jonsson and Waern 2008; Montola et al. 2009). The physical world affords seemingly infinite possibilities, meaning players are always able to produce "soft" events, outside the awareness of the game architecture, but still in relation to the game (Jonsson and Waern 2008). To capture some of these soft events, players can be monitored through direct surveillance and accounts thereof registered in game architecture (Crabtree et al. 2004; Montola et al. 2009). To assist in picking up on soft events, players can also be tasked with self-reporting, in the form of diaries (Montola et al. 2009; Jonsson et al. 2007).

Perhaps not part of the game state, per say, but important in monitoring a game mastered game, is any meta-level information, e.g., game master notes instructing other game masters on the state of the game (Montola et al. 2009).

Support Decision Making

To support game master decision making in-game, the potentially massive amounts of event information during monitoring must be dealt with. Additional information to aid decision making includes semistatic information, such as player information (e.g., photo, contact details, emergency information, game relevant skills) or documented help on how to stage a specific event (Jonsson et al. 2007). Automation aids game masters in decision making but obviously reduces game mastering, leading increasingly to a fully automated experience. One option to reduce game master load, without increasing automation, is to provide support tools, e.g., in the form of specialized GM interfaces or log analysis tools (Montola et al. 2009; Broll et al. 2006; Dow et al. 2005). Support tools convert or condense event information into a human consumable format. Another option is to cast nonplayer characters (NPCs) (Souza e Silva and Sutko 2009) in, to offload game master responsibilities (Jonsson and Waern 2008) achieving a more decentralized orchestration (Crabtree et al. 2004). Once game masters have made decisions, each decision must be actuated into the game.

Influencing the Game State

For a technology-sustained pervasive game, a common way to actuate change in a system, in run-time, is to directly alter the internal state of the game engine, i.e., alter variables in the game's data space (provided it is possible to access it) (Jonsson et al. 2007; Jonsson and Waern 2008; Hansson et al. 2007; Broll et al. 2006). Depending on the architecture, not all modifications are possible in run-time, and in such a situation the system must be brought offline to make necessary modifications (Hansson et al. 2007). Manually manipulating variables in the data space can be cumbersome when authoring lots of content. Developers of a game can attempt to anticipate what part of the data space game masters need access to and build an appropriate GM interface to it.

Although important for relaying observed events in monitoring a game, communication also plays an important role in influencing the game state, e.g., by pushing information directly to the players (Jonsson and Waern 2008). Communication can be either diegetic or nondiegetic (Bergström 2011), with the nondiegetic channel being particularly important to communicate out of the context of the game, in case of emergencies (Jonsson and Waern 2008). ("The 'diegesis' of a story consists of whatever is true *in that story*. Diegetic elements are 'in the story';

non-diegetic elements are not." (Bergström 2011, original italics)) Communication channels can be uni- or bidirectional.

State of the Art

There is a class of pervasive games, which are "technology sustained," relying on computer simulation to maintain game state and react to player activities; these games can be understood as "computer games interfacing with the physical world" (Montola et al. 2009, p.164). Technology-sustained pervasive games are contrary to "technology-supported" games, where not all game activities are supported by information technology (Montola et al. 2009), i.e., do not necessarily require a game engine. According to Broll et al. (2006), game engines for pervasive games do not differ entirely from computer games engines because "while the overall game is a mixed reality application combining the real [physical] and the virtual, the game engine actually does not need to be aware of this fact."

In a survey by Broll et al. (2006) important technologies for augmented-reality pervasive games have been summarized. Broll et al. (2006) mention the development of a pervasive game engine as "the logical next step," but, unfortunately, do not discuss the details of what constitutes a pervasive game engine, e.g., in relation to concepts such as persistence, interoperability, game mastering, and communication.

A recent survey, by Kasapakis and Gavalas (2015), aims to classify pervasive games into age generations based on technologies used. The survey is limited to 18 pervasive games, e.g., not containing tabletop games, smart toys, and trans-reality games, even though being mentioned as subgenres in the articles' related work. Kasapakis and Gavalas (2015) state that "the game engine organization model is largely dictated by the game scenario to be supported." If a general-purpose pervasive games engine is to be created, commonalities between game technologies must be found, e.g., support for a virtual persistent world. Kasapakis and Gavalas (2015) continues that the "current technological status favours [sic] always-on connectivity, hence, centralized models"; this is not entirely correct since, "always-on connectivity" relates to persistence, which can also be obtained through decentralized models.

In a recent publication by Kamarainen et al. (2014), the subject of cloud computing is discussed as a possible solution for pervasive and mobile computing, allowing the "end-user device to offload computation, storage, and the tasks of graphic rendering to the cloud." Kamarainen et al. remark that latency is the "main challenge" for cloud gaming, with most interactive games requiring response times that only "local deployment scenarios" can deliver. As a solution, they "propose to use [a] hybrid and decentralized cloud computing infrastructure, which enables deploying game servers on hosts with close proximity to the mobile clients." To exploit local resources, the Fun in Numbers (FiiN) platform features a distributed multitiered (i.e., four layered) large-scale architecture (Chatzigiannakis et al. 2011). The FiiN architecture supports more than one game engine, with each engine being the "local authority for each physical game site" (Akribopoulos et al. 2009). All game engines are coordinated by a centralized topmost layer.

The bottom layers of the FiiN architecture enable support for ad-hoc networks and Internet of Things (Gartner 2014). The problem with the FiiN architecture is that it is unclear exactly what types of pervasive games are supported. Pervasive games are defined in the FiiN publications as "games played in the physical space, indoors or outdoors, using mobile handheld devices, context-awareness, and in certain cases some degree of infrastructure and scripting." Chatzigiannakis et al. (2011) make no distinction between technology-sustained or technology-supported pervasive games, even though technology-supported pervasive games do not necessarily require a game engine, i.e., the infrastructure to enable them is very different. Akribopoulos et al. (2009, original italics) state that FiiN targets "mainly games that *involve multiple players, rapid physical activity, gesturing*, … *and less storytelling-based games*," which could account for why game master interfaces are not present in the architecture (Nevelsteen 2015).

Technology-Sustained Pervasive Games

Nevelsteen (2015) provides an extensive systematic review into pervasive games. Concentrating on technology-sustained pervasive games, a feature set is derived that describes characteristic features of a would-be pervasive games engine. These features can be considered a set of informal requirements from which a set of formal requirements can be drawn. Using the feature set, a virtual world engine was chosen as being in the same "product line" (Bass et al. 2013) as a would-be pervasive games engine, based on the shared trait of a persistence. The component feature set and the choice of a virtual engine as pervasive engine, by Nevelsteen (2015), are verified through the case study of the pervasive game called Codename: Heroes.

Component Feature Set

Having surveyed a total of 59 pervasive games/projects and 27 technologies, the following is a summary of the derived feature set for a would-be pervasive games engine (Nevelsteen 2015):

Virtual game world with world persistence: a spatiotemporal instance, with interacting virtual elements (at least one of which being the player); a game world that overlaps with both the virtual and the physical world; a world that continues to exist and develop internally even when there are no people interacting with it (persistence); and ubiquitous availability through a reliable architecture.

Shared data space(s) with data persistence: a common shared data space, with coordinated communication to it, and data persistence in the event of a shutdown or system failure, i.e., fault tolerant and recoverable.

Heterogeneous devices and systems: support for nonstandard input devices, comprised of sensors and actuators, that form an interface (Nieuwdorp 2005) between the player and the game; resolution of interoperability issues through a device abstraction layer; and the use of service-oriented architectures or the offering of such services.

Context awareness: context information, e.g., location, body orientation, available resources including network connectivity, proximity to surroundings or noise levels; context information is obtained through sensor enabled heterogeneous devices or service-oriented architectures; dealing with uncertainty in position localization or networking.

Roles, groups, hierarchies, permissions: various roles for player and nonplayer characters, organized in groups or hierarchies; different permissions or privileged information for the various roles or organizations, perhaps through an entirely different interface to the game.

Current and historical game state: including semistatic player info; a view of the current internal game state, e.g., through direct inspectable properties or through a specialized management interface; a historical perspective of the game state, e.g., through the logging of event data for post-game analysis; or any meta-level game information, such as game master documentation.

Game master intervention: the semiautomatic execution of the game through game master intervention in run-time, e.g., by directly manipulating the internal game state or through specialized interfaces, that potentially translate massive amounts collected game data into a human consumable form; game master intervention can be provide by a service-oriented architecture.

Reconfiguration, authoring, and scripting in run-time: in the pre-game phase (e.g., for location adaptability) that can be extended into the in-game phase; data-driven reconfiguration of software, hardware, and devices; dynamic story and content through content generation in-game; changing of the game rules through data-definition or run-time languages; autonomous agents; or the simulation of events for the Wizard of Oz (Dow et al. 2005) technique (see Section 2.3.8 of (Nevelsteen 2015)).

Bidirectional diegetic and nondiegetic communication: through various channels and/or interfaces.

Many of these features are quite generic (e.g., current and historical game state) and so are supported by engines in the domain of computer video games. Features more specific to pervasive games are heterogeneous devices and systems; context awareness; game master intervention; reconfiguration, authoring, and scripting in run-time; and bidirectional diegetic and non-diegetic communication, e.g., nondiegetic communication is required in a virtual world but not as pronounced as in a pervasive game where it is needed to cope with social expansion.

Challenges and Open Issues

The problems, caveats, and disadvantages highlighted through the case study of Codename: Heroes (Nevelsteen 2015) serve to highlight challenges and open issues for the creation of a would-be pervasive game engine. These challenges include: (1) using distributed and decentralized architectures; (2) extending ubiquitous computing; (3) interoperability; and (4) creating game master interfaces and tools.

Distributed and decentralized architectures: Exemplified by Demeure et al. (2008), fully decentralized architectures exist, where the game state is not centrally controlled and only shared with other clients when opportune. A challenge exists pertaining to the extent that a decentralized architecture can be utilized for games. Issues arise as how to: maintain security, maintain a shared data space, and prevent cheating (Yahyavi and Kemme 2013); gather and persist data (e.g., for monitoring); or build dynamic user interfaces. To deal with the scalability issue, virtual world engines already exist that use a centralized distributed system of servers for load balancing (e.g., BigWorld (2011)), so utilizing such techniques for pervasive games seems evident.

Extending ubiquitous computing: Devices and systems have the potential to offer richer context information for context awareness, e.g., the incorporation of body metrics or social relations. Ubiquitous computing remains a challenge, with open issues: increased utilization of context awareness; reduction of soft events (e.g., in communication); focusing on technology that can be effectively pushed into the background (e.g., for ubiquity of access and diegetic communication); and obtaining ubiquitous persona and presence (Dionisio et al. 2013). The latter recognizing that a player's identity is made up of the sum of their interactions with the game, e.g., crossmedia through different devices or interfaces. The amount of uncertainty in ubiquitous computing has been reduced considerably; early writings on pervasive games include much on mobile networking issues, which are solved in mainstream technologies today but some issues are still critical, e.g., losing connectivity by switching between WLAN and mobile networks. A partial solution could be that of delay-tolerate network communication, used in FinN (Akribopoulos et al. 2009), to obtain an eventually consistent game state in their distributed system.

Interoperability: In 2004, Greenhalgh et al. (2004) set out to interconnect heterogeneous devices with the EQUIP/ECT technologies. Broll et al. (2006) state interoperability in pervasive games to be a "well-known problem." And, a number of years later, Branton et al. (2011) dedicate an entire publication to deal with the "important challenge" of interoperability through standardization. Many innovations, such as new languages or middleware, are sited by Branton et al. (2011) as partial solutions, but compatibility between web services was noted as "largely lacking." Since some game engines and service-oriented architectures are already distributed systems, and they interact, then interoperability is an issue between heterogeneous distributed systems as well, i.e., similar to multi-cloud network communication (Singhal et al. 2013). Interoperability remains a challenge with the amount of heterogeneous devices and systems increasing and becoming more diverse (Gartner 2014).

Game master interfaces and tools: Because it is beneficial to build reusable game engines, it seems reasonable to infer that reusable game master interfaces and authoring tools should also exist (e.g., see (Broll et al. 2006)). Some game master tools have already been created (e.g., for mobile games (Paelke et al. 2008) and authoring tools for location-based games (Oppermann 2009)), but a

more general reusable approach remains a challenge (Guerrero Corbi 2014; Benford et al. 2009). Open issues are: capturing soft events and entering them in the game state; reducing the potential overload of data into a human consumable format; creating interfaces and visualizations that are applicable to a wide variety of games; and generating interfaces and visualizations that cater to the activity of game mastering rather than just presenting information.

Conclusion and Discussion

Computer video games have existed for decades, with reusable game engines to drive them; the major incentive for employing a reusable game engine being reduced development time and cost (Lewis and Jacobson 2002; Bass et al. 2013). Technology-sustained pervasive games can be understood as computer games interfacing with the physical world, so computer game engines can be used to stage a pervasive game (Nevelsteen 2015). Currently, there are no reusable game engines available for pervasive games, but herein a component feature set has been presented for a would-be pervasive games engine, including the challenges and open issues uncovered during the case study verifying the feature set.

According to Jonsson et al. (2007), pervasive games need a sensory system to monitor the physical world. Pervasive games are known to make use of "nonstandard input devices" (Nieuwdorp 2007), and with the rise of the Internet of Things (Gartner 2014), access to Internet of Things could potentially serve as such a sensory system. Considering the use of nonstandard input devices in pervasive games and the rise of the Internet of Things, how will this affect pervasive games remains an open question.

Synonyms

Persistent environment; Persistent state world; Persistent world

Definition: "World Persistence"

Bartle, in 2003, stated that a persistent virtual world "continues to exist and develop internally even when there are no people interacting with it" (Bartle 2003). Bartle's criterion that the world "continues to exist" can be referred to as "world persistence" (Nevelsteen 2015), with the element of time, as a minimum, continually "developing internally" within the world, i.e., "a [persistent] virtual world cannot be paused" (Bell and Robbins-Bell 2008).

Introduction

In popular discourse, world "persistent" or "persistence" is often related to a feature to mean the continued existence of that feature, e.g., persistent storage meaning nonvolatile storage. This entry focuses on world persistence. Concepts such as world persistence and data persistence are often erroneously used interchangeably, and ambiguity creeps into the meaning of combined terms when using a particular word order, e.g., virtual-"world persistence" versus a persistent-"virtual world." If pervasive or ubiquitous computing is taken into consideration, which take places in the physical world, persistence once again can be used to describe the world. How this relates to other forms of world persistence is not well established. Various definitions and descriptions of "world persistence" exist (Bartle 2003; 2010; Girvan

2013; Bell and Robbins-Bell 2008; Lankoski et al. 2004a; James et al. 2004), but a clear overarching definition is lacking when taking into account the physical world. This entry isolates the concept of "world persistence" and discusses it in relation to the physical, virtual, and game world. The simulation of world persistence, namely, pseudo-persistence, is taken into account.

Physical, Virtual, and Game Worlds

To resolve the ambiguities around the usage of "persistence," the concept of "world persistence" is first isolated with respect to the physical, virtual, and game world.

Physical world persistence – Lankoski et al. (2004a) state clearly that "persistence is a quality of actual life and the physical world," i.e., the physical world has world persistence; it continues to exist and cannot be paused.

Virtual world persistence – In 2010, Bartle relaxed his persistence criteria, removing the need for internal development, stating: "if you stop playing then come back later, the virtual world will have continued to exist in your absence" (Bartle 2010). This is a logical step, because, beyond the element of time, "internal development" is a quality related to the "worldliness" of the world, rather than its persistence. Girvan (2013) states that world persistence is the "defining characteristic with which to distinguish between video games and virtual worlds." (It should be noted that virtual-"world persistence" is not the same thing as a persistent-"virtual world"; the latter being a virtual world that supports world persistence, which can be a tautology depending on the definition of "virtual world" used.) For their definition of a virtual world, Bell and Robbins-Bell (2008) use Bartle's original persistence criterion to differentiate between video games and virtual worlds, stating that "a virtual world cannot be paused." Lankoski et al. (2004a) corroborate the non-pausable criteria, stating "a game without a pause or ending is persistent by definition."

Game world persistence – Nieuwdorp (2007, original italics) derives that pervasive games can be discussed from two perspectives, a technological one "that focuses on computing technology as a tool to enable the game to come into being" or a cultural one "that focuses on the game itself." Using these two perspectives allows for another type of persistence to be identified, namely, "game world persistence" (Nevelsteen 2015). Technology can be created to maintain virtual world persistence (from a technological perspective), but designers of a world can explicitly choose to have certain events not to "continue to exist" (from a cultural perspective); game content is "reset" (Keegan 1997; Brennan 2009), so that it can be experienced repeatedly, e.g., in a persistent multiplayer game, having an important adversary stay dead keeps new players from experiencing that game content, so the adversary's death might be reset.

Other possible types of persistence related to world persistence are "data persistence," ensuring that "world" data is not lost in the event of system failure, e.g., in a world that "retains records of player data indefinitely" (James et al. 2004); "network persistence," maintaining a virtual connection between networked devices or systems that form a world, e.g., in a mobile networking setting; and "persistent activity," constant player activity under the influence of real world events, e.g., "bio breaks" (Nevelsteen 2015).

Pervasive Games and Ubiquitous Computing

Above it is stated that the physical world is persistent; since pervasive games blend with the physical world (Benford et al. 2005), pervasive games are persistent game worlds, sharing the trait of persistence with virtual worlds (Souza e Silva and Sutko 2009). In technology-sustained pervasive games (contrary to technology supported) (Montola et al. 2009; Nevelsteen 2015), it is sometimes beneficial "to exploit the coextensive virtual world as a 'behind the scenes' resource for

coordinating and managing devices and interaction in the physical space" (Greenhalgh et al. 2001). But, as explained in Nevelsteen (2015),

> in pervasive games, exact times of play (when the player is in the game world) can be expanded temporally, making times "remain uncertain, ambiguous, and hard to define" (Montola et al. 2009). A solution is to make the game world available at all times, as suggested by one of the definitions of pervasive games, "a game with a persistent presence in the real [physical] world, and thus available to the players at all times" (Nieuwdorp 2007). Another solution is to simulate world persistence, by either scheduling play times around when the world is unavailable or by making relevant player/world data available at least when those player(s) reconnect to the game (Söderlund 2009).

This means that if a pervasive game is technology sustained and the game is to be persistent, the technology needs to be available to the players when they want to access it (provided the game, from a cultural perspective, requires the technology to be accessible).

Related to pervasive computing rather than games, Lankoski et al. (2004a) state that the "nature of persistence is closely related to the nature of ubiquitous as understood in the ubiquitous computing research field."

Pseudo-persistence

A difficulty with identifying world persistence is that it can be simulated without raising awareness to the player. One example has already been given above; if the world is made available to players at all times they want to access it, it is seemingly always in existence; a straightforward way to achieve this is to have scheduled play times around downtimes (Nevelsteen 2015). Similarly, this access on demand can be applied to the events in the world as well. Söderlund (2009) describes a "pseudo-persistent" virtual world made up of a collection of mobile devices; world data is loaded and made available at specific times when players, relevant to that data, are playing. And, in a game, events can be generated during down times to simulate the passing of time (Wikipedia 2015; Nevelsteen 2015). Herein, I generalize the meaning of pseudo-persistent to mean the simulation of persistence.

Persistence in Practice

The Songs of North (Lankoski et al. 2004b) is a pervasive game (i.e., persistent in the physical world) that makes use of a coextensive persistent virtual world (the "spirit world"), as an invisible "behind the scenes" resource; the "spirit world and its physical counterpart thus share time and space" (Lankoski et al. 2004a). By logging in, a player can access the virtual spirit world, which was required to support world persistence. Lankoski et al. (2004a) state that "the game is possible to play without logging in . . .," i.e., the rules of their game dictate, from a cultural perspective, that their game can be played without logging in. What is problematic is that Lankoski et al. (2004a) continue by stating that ". . ., like any other persistent game: this happens for example when two players meet in the physical world or send an SMS or phone to each other." If from a cultural perspective, the virtual environment is deemed a critical resource for playing the technology-sustained pervasive game and that resource becomes unavailable (the environment does not support world persistence), then players trying to access that resource and failing would be interrupted in their persistent play.

Persistence is said to be the "defining characteristic with which to distinguish between video games and virtual worlds" (Girvan 2013). Player(s) of the video game called Doom (id Software 1993) have the option to pause the game, making the world fail to be persistent. But it would be trivial to remove this feature; would this altered version of Doom support world persistence? Typically player(s) of Doom, start their Doom client software, go through a load/log in procedure (with the world hosted on one of the player's systems) and enter the world. If all players stopped playing and shut down their

system, the world would obviously not persist, i.e., stopped as soon as the host was shut down. If Doom was left running, one might argue that Doom supports world persistence; however, the world state of Doom is only stored (i.e., data persistence) through manual player intervention. In the event of system failure, the world state would be lost, i.e., no world persistence. In a multiplayer game, if at least one player remained to keep the world running by manually persisting the data (with the other players coming back later to find the virtual world to have continued to exist in their absence), would the world be persistent? In this case, the definition by Bartle in 2003 is superior to that of 2010 because of the clause that there must be "no people interacting with it" (Bartle 2003). This allows Doom, which is kept alive through player interaction, to be classified as pseudo-persistent. Similarly, world persistence could be simulated, if all players agree on scheduled play times to access the world (i.e., the host would be available specifically during those times), but the world will be "frozen" during downtime. As a solution, pseudo-persistence could be used to give the illusion of a world "developing internally." It should be noted that it is almost impossible to have a truly persistent world; large-scale virtual worlds (e.g., World of Warcraft (Blizzard Entertainment 2004), which supports world persistence, with "instance" dungeons (WowWiki.com 2015) that are ephemeral) often have maintenance hours or days.

Bartle cocreated MUD (Trubshaw and Bartle 1978) and so it is assumed that his criteria were based on his own technology. Typically, the world of MUD is hosted on a server with players accessing the world through networking. Ideally, the world is then continually in existence and available, with players unable to pause the world, i.e., MUD supports world persistence. It is possible to access a MUD from a local machine as a single player game; although not the intended use, it is possible to compare MUD and Doom this way. When MUD is used locally, if the player shuts down the computer, the world will be frozen, similar to Doom (this could be considered a maintenance break). The major difference between Doom and the local version of MUD with respect to the world persistence definition is that MUD still does not support the pausing of the world and MUD periodically stores the world state (i.e., data persistence), guaranteeing world persistence if the computer is left running.

Above, a world where certain events are reset periodically is said to lack game world persistence for those events. Taking this to the extreme is what has been referred to as a Groundhog Day MUD, "where all the elements of the MUD's world (excluding the users [players]) are reset to some predefined state" (Keegan 1997). This is a borderline case, which can be solved by asking the question, is there something in the world that is and has been under the constant influence of the world's time? If everything in the world is reset, excluding the player data, then the player data has game world persistence, but the world lacks persistence. The world would be equal to the concept of an instance in existence today, which explicitly does not support world persistence. The separation of world and player data is more distinct in the multiplayer game of Diablo (Blizzard Entertainment 1996), where players first gather in a virtual lobby, before venturing into instance dungeons. The dungeons are created for one play through and reset, but player data is preserved; afterwards players are sent back to the lobby where they can choose to start another dungeon. Diablo can be classified as pseudo-persistent, where the virtual lobby supports world persistence and player data is loaded in the instance when relevant players are playing. Having player data persistent is perhaps equal to what Lankoski et al. (2004a) refer to as "persistent game identities."

Conclusion and Discussion

This entry isolates the concept of "world persistence" and discusses it in relation to the physical, virtual, and game world. The simulation of world

persistence, namely, pseudo-persistence, is taken into account.

Synonyms

2D animation; Digital process; Digital production; Pipeline; Vector

Definition

Pipeline is commonly used in animation production processes; it describes the process of working on a piece, episode, or film. It explains the route that the production follows to be able to carry out and finish, through the different departments involved.

Introduction

To understand the processes of 2D vector animation, it is necessary to take into account the historical evolution of the technical advances that have allowed an advance in the animation series.

Hanna and Barbera allowed us to create a streamlined pipeline for animated television production, clearly specifying the processes to be followed in order to optimize the production times required by television.

The advent of digital techniques has made it possible to speed up production processes and reduce budgets. In addition, a favorable result has been obtained in the creation of new visual styles in the 2D animation series, leaving aside Hanna-Barbera's compact designs.

Background and Technical Evolution

The origins of digital animation lie in the history of technical development itself. The interest in making moving images helps the technical development of cinema. Animation is born as an almost handmade process, which evolves to digital, but without losing the artistic aspect.

The first known attempt at a projection animation dates back to 1640, when the German Athanasius Kircher invented the magic lantern. Kircher made drawings on glass plates that he projected, thanks to the new invention. He added position changes on the characters, like a man who slept and opened and closed his mouth in a mechanical way (Garcia 1995).

As a reference for entertainment animation, the first optical toys such as the zoetrope (It consists of a cylindrical drum that restores the continuous development of a repeated action. A strip of paper is placed inside the drum, the length of which is equal to the perimeter of the inner circumference of the drum. The strip is drawn with a figure broken down into phases of movement, as many as there are slots in the drum. The drum rotates around its center, and looking through the slots, you can see how the various drawings acquire movement.) or the praxinoscope ("The purpose of the apparatus is to obtain the illusion of movement, not limited to the repetition of the same gestures in each turn of the apparatus, as is necessarily the case with all known apparatuses: zoetropes, praxinoscope, etc., if not the contrary, having an indefinite variety and duration and thus producing true animated scenes of unlimited development (Beaudet 1982).") were created. Both devices represent the phases of a short cyclic

movement. This technique is the same as the one used in digital GIF (Graphic interchange format (GIF) a system of compressing the information of a digital image employing a restricted palette to reduce its file size.) files or in the animation sprites (Chong 2010, p. 120) used in videogames. In 1877 Emile Reynaud created a praxinoscope with a tape of longer images, which allowed her to create animations with a plot.

> In these tapes he already used modern cartoon techniques, such as the dissociation of figures and decorations, successive casts on transparent sheets, etc. We can say, then, that the cartoon was born before the cinema itself. (Gutierrez Espada 1979)

With the arrival of the cinema in 1885, thanks to the Lumière brothers, a camera was used to record the images, and Alfred Clark introduced the handwheel system, which took images frame by frame. With this technique, Emile Cohl (Furniss 2008, p. 130) makes a series of works through drawings in front of the Fantasmagorie camera, where the author simplifies, schematizes, and iconizes the characters with the need to reduce the work to be done. Winsor McCay (Bendazzi 2002) works directly on paper, fitting the sheets into a box, to prevent inter-frame movement, reusing drawings of poses and movements.

John Randolph Bray, another cartoonist, discovers the industrial possibilities of cartoons. In 1913, in the artist's dreams, he introduced a new technique, he knew the repetitive printing used in newspaper presses, and applied it to the printing of backgrounds in order to later draw the animation of the characters, saving the redrawing of backgrounds. In 1915, together with Earl Hurd, they patented the "cel system" (Laybourne 1998). The system consists of carrying out the animation on transparent cel to be recorded on top of the backgrounds. This technique has been used until the computer age. The acetate technique separates the work from the animation and the backgrounds and therefore provides a specialization. In the cel the paper drawing is traced and then filled with opaque paint, all this by dividing the work by departments.

If we look at the first designs of the characters, they all look like rubber, with very soft bodies. Pat Sullivan and Otto Messmer with Felix the Cat, Max Fleischer with Betty Boop, and Walt Disney with Mickey Mouse, among others, are characters who have a base of circles and round shapes that allow them to move their movements dynamically and give them that rubber character, called Rubber Hose, imitated in 2017 in the video game Cuphead (https://www.cartoonbrew.com/videogames/cuphead-overflows-classic-cartoon-surrealism-153824.html).

Another of the techniques that particularly stands out in the early years is the one used by Lotte Reiniger (Furniss 2008, pp. 237–238) in 1926, with *The Adventures of Prince Achmed*, which, based on shadow theater, produces an animation of black silhouettes on a white background. This technique requires that all the different parts and movements of the characters are generated, and then the performance is done under camera. This technique, at the moment of digitalization, is now called puppet animation, with all the advantages of digital technology.

In the early 1940s, the UPA (Amidi 2006) studio was created, where they began to create more schematic animations and simplified and easy to animate characters. All this makes it possible to adjust to postwar budgets, and this influences the use of simpler visual resources that show more aesthetic pieces. This new style of animation influences artists such as Chuck Jones in Warner or the limited animation series that Hanna-Barbera has been producing for more than 30 years.

On the other hand, the first experiments with animation and soundtracks by John Whitney arrived. In 1961 he presents Catalog (Chong 2010, p. 164), a piece of complicated optical shapes made frame by frame. Whitney argued that technological innovation will provide us with the means to develop a new audiovisual. Computers are the only instrument that allows us to create music related to graphics and colors in motion, although their complementarity is still experimental, but good results are expected.

> The synthetic image, which is so because it only exists in the electronic memory, and is reflected in its high-definition graphic output, when programmed for this purpose, allows the creation of a dynamic reference of space and object, in which

> every image and every creative will on it is possible. (Eguillor 1986a)

The technical advance continues in 1985 with Disney and introduces the video cameras to perform linetest (Filming of the animation in its first stage of production. Call also 2D pencil test.) and the APT (animation photo transfer) to scan the drawings. With the Disney CAPS (Computer Animation Production System) software, the scanned drawings were transferred to digital ink and paint, making the process easier. This software is developed by Pixar on behalf of Disney. It is used to scan and paint each drawing. To all this we must add the creation of other professional animation software, such as Animo, RETAS or Toonz, that follows the Disney CAPS and is standardized in animation production. All these systems take the digital treatment as much as has been possible until now in analog animation: multiplane, sound, or overlays. New technologies open up new ground for artistic creativity:

> We will have to wait for the not too distant future, and thanks to this, the cartoon field will reach a level of artistic consideration that it has only achieved on a few occasions. Although it won't be exactly cartoon as it is normally considered. Although the process of the synthetic image is analogous to that of the animation (the brain does screen readings on the screen, as in frame by frame animation), I think it is necessary to talk about computer image processing rather than cartoon, with a plastic quality as good as paint. (Eguillor 1986b)

Macromedia Software created FreeHand and Flash design programs based on vector graphics in the 1990s. FreeHand is dedicated to graphic design, and Flash is dedicated to creating simple animations for the web using vector images with an interactivity component. It allows drawing in a very intuitive way for the user; in the same way, it works with frames, allowing simple animations and a few megabytes that can be shared on the Internet. In the early 2000s, Macromedia joined the Adobe group, which continues to develop the tool. Years later, vector animation tools such as Toon Boom or Anime Studio Pro were created. The arrival of graphic tablets, which allow drawing on the screen, has brought a breakthrough in the processes of drawing, design, and animation or design, which allows us to draw directly on drawing, animation, or design software, on macOS, or Windows systems.

In the late 1980s and early 1990s, television consumption increased, and this created demand for the cartoon product (Holz 2017). The worldwide spread of the personal computer and user-friendly animation software opens a new path. Lowering the costs of creation and facilitating accessibility, distribution and exhibition through the Internet. We can say that there has been a second revolution in animation as with the advent of sound and color. Technology continues to advance and cartoons have always been on a par. Any technical advance was soon used in the industrial products of the environment. By solving certain phases of the production process, the technology allows the team to spend more time on other, more aesthetic or stylistic facets of the production process, giving a wider margin in the visual sense. A clear example in Cartoon Saloon's Puffin Rock series (https://blog.smithmicro.com/2015/10/06/anime-studio/how-anime-studio-is-used-to-produce-the-show-puffin-rock/).

Production Pipeline with Vector Animation

The realization of an animation series follows the basic guidelines: preproduction, production, and postproduction. The use of vector technology allows you to modify processes that affect time, costs, and visual styles.

Preproduction Stage

In the preproduction phase, we start with a budget to develop the series. The pilot episode has been conducted earlier to secure the necessary financing; otherwise, it would not be possible. The production team distributes all the work to be done on a production schedule, drawing up a list of all the necessary human and technical resources. With the help of the entire team, the premises for each episode are established so that they can be developed by the script teams, as the design team begins to develop the characters and props. In a traditional animation production (handcrafted or digital), the reference material that is generated on

paper and then scanned and colored in digital, or also in digital form, serves as a visual reference for animators, but that material is not reusable. But in a vector production, the development is much more detailed. The art director's team, along with the director and animation supervisor, establish the visual and style guidelines to be followed. The design team not only makes the designs but also animates and demonstrates how the characters should be moved. In this way they generate a whole library of digital files of characters, props, and movements, which the animators use throughout the series, following the style set by the director and art director. These are guidelines that are followed when designing the characters, to optimize the animation during the production phase.

- The character design is broken down into layers or levels of each part of the body. Any character in the series looks like a united whole, but has parts to animate (Fig. 1).
- Reuse of the parts of the body is only drawn once, hence the importance of preproduction, to make all the material required in character. The characters function like puppets. The animator is dedicated to the animation of the expressiveness without the need to draw.
- Careful planning and attention to detail are marked from the development of each character and should be reflected in the visual guide. The character in his visual development has been raised how the character will move its parts and its limbs.
- Simplified, cyclical backgrounds and straight sections. With vector drawing tools, backgrounds are created with loose elements, making it easier to reuse or change the color of the scene (Fig. 2).

Cyclic or repetitive backgrounds are those that are seen on the screen in a race that are repeated elements every so often; again using the editing tools, you can break this repetitive action (Fig. 3).

When creating a long background, we must introduce different elements along the background. Each time the movement cycle changes, we vary the elements to make it different each time (Fig. 4).

- Walking or running cycles are simplified. Any cycle or animation that can be reused. The walking cycles are carried out with few poses, achieving the sensation of movement (Fig. 5).
- The main use of the characters' views is the ¾, which allows better transmission of the characters' expressions and actions.
- Lip sync is designed with a limited number of phonemes, with no intermediate drawings (Fig. 6).
- The use of squash and stretch (It is one of the 12 principles of animation. The exaggeration and deformation of bodies and other parts, as if they were flexible, serve to achieve a more comical or more dramatic effect. Stretching also helps to give a feeling of speed or inertia.) can be a good expressive resource and sometimes helps the expressiveness of animation (Fig. 7).

Pipeline of 2D Vector Animation in Television Series, Fig. 2 Background base design

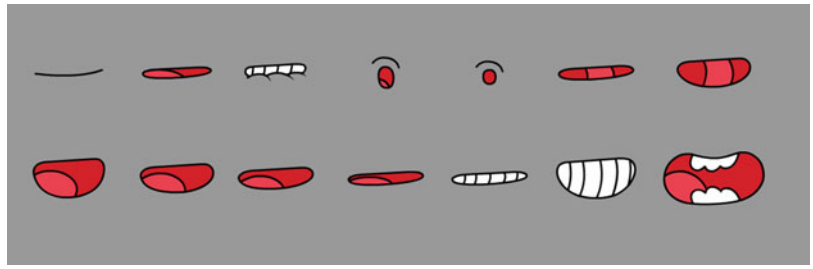
Pipeline of 2D Vector Animation in Television Series, Fig. 3 Background mount to repeat

Pipeline of 2D Vector Animation in Television Series, Fig. 4 Elements to make a background

- The design of trousers or legs of a single color, to make fewer drawings in the animation. Some of the supporting characters use this method.
- The character design becomes symmetrical and is easy to reuse. The introduction of asymmetrical characters as protagonists shows an advance in limited animation (Fig. 8).
- The visual entity marked by the limited color palette is always necessary and gives a unique character to the series.
- Special effects such as water, fire, liquids, etc. are defined graphically and animated.
- Simple animation as a way of life for a character, such as blinking or a simple gesture, is reflected in any scene (Fig. 9).

The Amazing World of Gumball, Samurai Jack, and Teen Titans Go! are some of the series that show an aesthetic, a very refined animation, very graphic, full of elements that can be animated without limitation.

Pipeline of 2D Vector Animation in Television Series, Fig. 5 Simplification of walking



Pipeline of 2D Vector Animation in Television Series, Fig. 6 Different mouths to lip sync

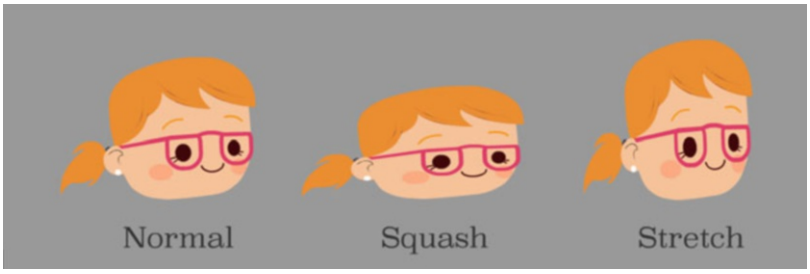
While all the design material is being produced and the scripts are being finished in stages, the reference dialogues, which are used in the creation of the storyboards, are being recorded. In the new animation series, the storyboarding phase is created directly with a drawing software, which allows you to work with the audio of the dialogue, and introduces more drawings of poses, camera movements, and other functions, which make it easier to create the episodes more dynamically. The piece that is obtained is an animatic (Is a series of still images edited together and displayed in sequence. More commonly, a rough dialogue and/or rough soundtrack is added to the sequence of still images (usually taken from a storyboard) to test whether the sound and images are working effectively together.), essential for the next phase, since it gives us as a result of the number of scenes divided by each episode, with all the characters, props, and backgrounds that intervene in the scene, including the reference audio of dialogues. In this phase we finish defining all the necessary backgrounds for each scene, designing each detail that intervenes in the action.

In this phase, all the necessary backgrounds are defined for each scene, designing every detail that intervenes in the action.

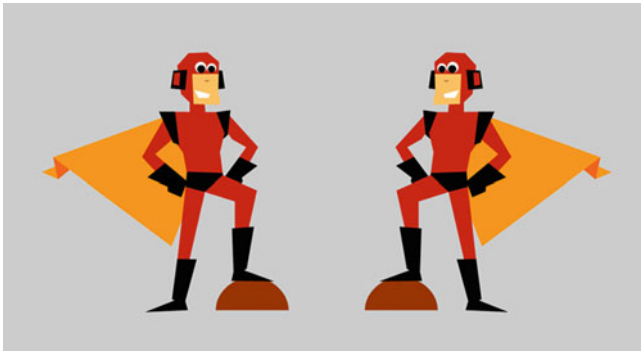
Production Stage

In this phase the technical layouts are made; these consist of generating the vectorial animation files, which are for each scene, adding all the necessary character libraries, props, backgrounds, and audios. The layout artist composes the scene with the reference material, so that it is ready for the animator.

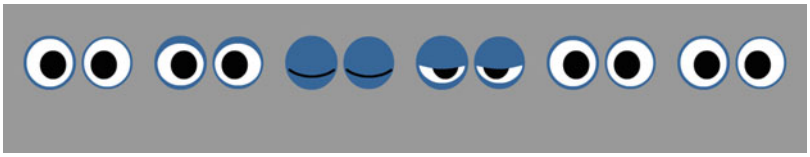
In the animation process, the animator is assigned a number of scenes to perform. The professional has all the material provided in the files generated in the layout but also has the visual and animation guides generated by the animation director in the preproduction stage.



Pipeline of 2D Vector Animation in Television Series, Fig. 7 Applying the squash and stretch to a head



Pipeline of 2D Vector Animation in Television Series, Fig. 8 Symmetrical character



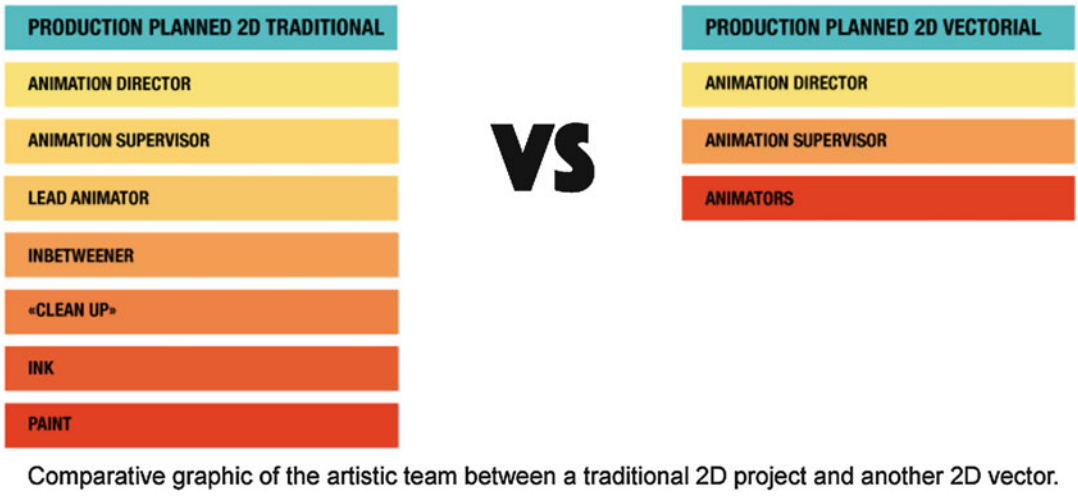
Pipeline of 2D Vector Animation in Television Series, Fig. 9 Frames of blink eyes

The vector animation process can be done by two ways:

1. One way is the traditional digital system, also known as tradigital, which follows the traditional processes but on vectorial drawing with animation software. The animator can use the material generated in the preproduction, to maintain the visual style. These animators are called key animators. This method will have a subsequent process of cleanup and final coloring that is carried out by an animation assistance team, which finishes the visual finishing of the scenes.
2. The other way used is known as puppet animation or digital cutout. The animator makes the scenes with all the preproduction material, does not have to draw, only animates the parts of the characters and objects, also makes the camera movements, and uses the effects that are in the library. The times of realization are shorter than with the traditional technique, since they have only one phase, and the scenes go directly to postproduction.

Postproduction Stage

The scenes of each episode are edited. The necessary sound effects are added to enhance the action and continuity of the scenes. If the previous dialogues are for reference, the final ones are recorded, to be mounted with the scenes. If the production of the series is more visually complex, a compositing process is performed. This consists of composing the scenes with the different layers, more complex camera movements, visual lighting effects, or FX. The music that accompanies each sequence is then performed, which is mixed with the episode, obtaining the master of the episode.



Pipeline of 2D Vector Animation in Television Series, Fig. 10 Production traditional 2D versus production digital 2D

Conclusions

The technological development has been present throughout the history of animation; the current use of digital tools allows professionals to have a better general concept of an animated production. This greater concept is reflected in a greater knowledge of the work and is therefore an advantage when it comes to carrying out a series of this type. The traditional animation production method has benefited from the technical advances brought about by the market:

- New animated cartoon channels have been created on TV and the internet.
- New studios have been founded, with new series proposals.
- 2D animation has been established in broadcasting channels.
- Development of 2D vector graphics and animation software.
- The search for new esthetics in animation.

The new technologies in animation have allowed a quick adaptation of the traditional 2D animation to the 2D digital animation, showing certain conclusions, which definitely show an advance in the sector and show a new way in the development of series (Fig. 10).

- The technical advances have allowed to reduce the times of production and to optimize processes, improving the quality of the productions.
- 2D software requires multifaceted artists to work as a team in the creative process, totally involved in the work flow.
- It requires detailed planning of the production in order to optimize resources and means. Good planning allows resources to be reused and so more efficient productions.
- The fundamentals of traditional animation are transferred to digital productions to further the evolution of the technique.
- Strategies and character design resources are established to make them easier to animate. Material is created with the idea of it being reused.

Cloud Imperium Games, London, UK

Synonyms

Asset creation; CG; Computer graphics; Procedural content generation; Virtual environments; Virtual reality

Definition

Creating large amounts of playable content is a problem that game developers often face when creating large-scale games. One approach to address this challenge is to program the computer to assist in creating this content, a method generally referred to as procedural content generation (PCG) (Freiknecht and Effelsberg n.d.).

Introduction

Virtual game worlds for modern video games are requiring constantly increasing time and resources to create this ever-increasing amount of content. Being able to procedurally assist the creation of such content can allow the creation of large environments of high detail and fidelity, which would be otherwise impractical to handcraft manually (Freiknecht and Effelsberg n.d.).

Generally, the procedural generation of content in different forms and small scale is established in the industry; however, not much work has been done in the field of creating and managing very large worlds such as entire planets (Carpenter 2011).

Procedural Generation Overview

Procedural generation is a computing method of creating data algorithmically, instead of manually.

This is usually achieved via a combination of human-created content and algorithms, combined with computer-generated (pseudo) randomness and processing power. In computer graphics or animated movies, it is often used to create 3-D models and textures (Ebert 2003).

In video games, it is typically used to help create larger amounts of content in a game, such as virtual landscapes, 3-D objects, character designs, animations, or non-player character dialogue. Depending on the implementation, advantages of procedural generation can involve generating larger amounts of content from a smaller file size and a smaller amount of input data, reduced manual work and (pseudo)randomness for gameplay variation (Eurogamer, Digital Foundry, Star Citizen Tech Focus, seamless scaling from gas giants to detail-rich alien worlds n.d.; PCGamer, Elite Dangerous n.d.; Structure system procedural generation n.d.; The BLDBLOG book, Procedural destruction and the algorithmic fiction of the city n.d.).

Driven by the need of making games more replayable, to reducing time and resource burden as well as to generate unique virtual environments, many Procedural Content Generation methods have been devised (See Freiknecht and Effelsberg n.d. for an overview).

A recent exciting evolution is the combination of Machine Learning and Procedural Generation. While researchers are redesigning methods from machine learning (ML) to solve PCG problems, the ML community has been inspired by PCG methods to solve a particular set of problems, in this context new opportunities such as procedurally generated learning environments. Although their origin can be traced back to games, we believe (procedural) generation algorithms can play an important role in creating more general machine intelligence (Increasing generality in machine learning through procedural content generation n.d.).

Large-Scale Generation in Games

There are several challenges to creating very large game worlds of planetary size.

One of the main problems is being able to produce far more content than could be physically stored in the memory, but doing so in such a way as to only generate on-demand what is needed around a given location, in order to minimize cpu, gpu, and memory utilization (Greuter n.d.).

Since the world size vastly exceeds what can be represented using 32-bit floating points numbers, precision becomes a large issue. On-demand collision/physics generation on client and server also needs to be implemented, since the collision representation for the environment is too large to be stored in the memory (Planetary generation and tools n.d.).

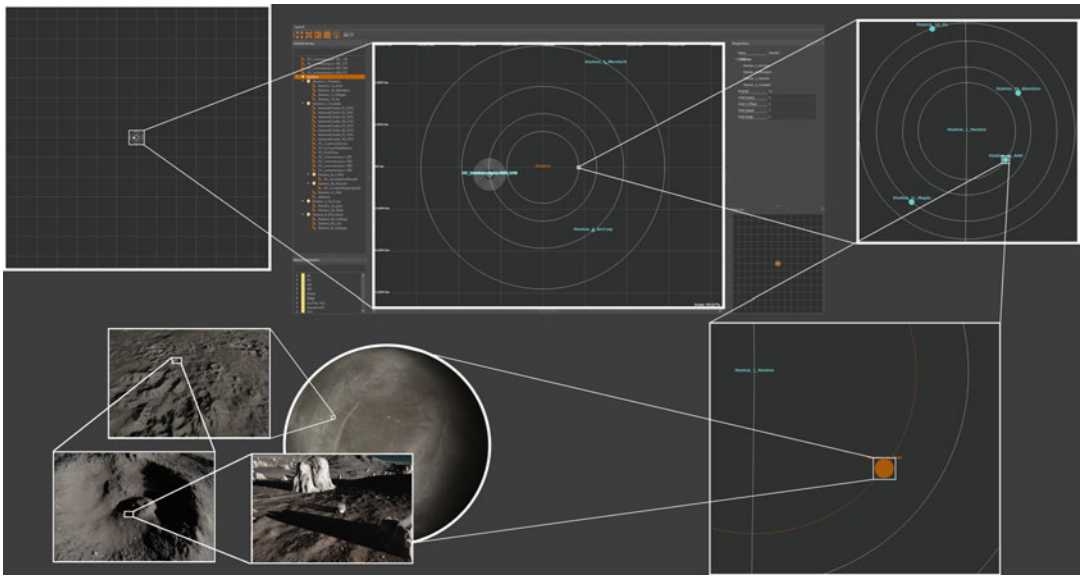
Planetary Generation in Games

A long-standing goal of planetary generation is to achieve seamless transitions between space and planets: fly to a distant planet, landing on it, getting out, and exploring its entire surface with no loading screens (Eurogamer, Digital Foundry, Star Citizen Tech Focus, seamless scaling from gas giants to detail-rich alien worlds n.d.; PCGamer, Elite Dangerous n.d.).

This process also requires the creation of custom planetary generation tools, to provide artists enough control over the planet's creation, but still having the process as much automated as possible due to the sheer size of the environment (Designing with Autonomous Tools: Video Games, Procedural Generation, and Creativity n.d.; Planetary generation and tools n.d.) (Fig. 1).

Conclusion

Currently, there are few games implementing planetary-scale generation and seamless transition from space to the planet in an online environment (Eurogamer, Digital Foundry, Star Citizen Tech Focus, seamless scaling from gas giants to detail-rich alien worlds n.d.; PCGamer, Elite Dangerous n.d.; Procedural Generation, No Man's Sky n.d.). As described in this article, this is typically achieved through a combination



Planetary Generation in Games, Fig. 1 Planetary Generation. Showing the sense of scale, seamless transition, and scaling from a solar system in open space down to planetary surface details (Eurogamer, Digital Foundry, Star Citizen Tech Focus, seamless scaling from gas giants to detail-rich alien worlds n.d.)

of procedural generation, tools, and human-driven input.

As games are striving to take place in progressively larger open-world environments, the generation of planets and associated ecosystems constitutes a promising branch of research and business development opportunities, especially when combined with recent machine learning approaches.

Player Abusive Behavior Detection

Jeremy Blackburn
Department of Computer Science, University of Alabama at Birmingham, Birmingham, AL, USA

Synonyms

Player behavior; Toxic behavior

Definition

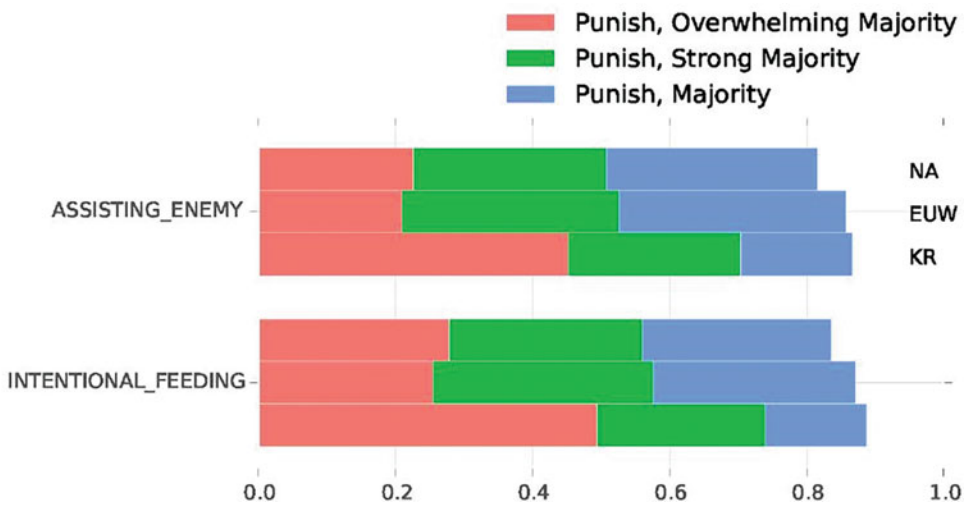
Player behavior = The way a player acts and conducts themselves within a game.
Toxic behaivor = A player's behavior within a game causes harm to other players by psychological or mental means.

Introduction

Antisocial behavior that can have lasting effects and to which numerous players are exposed to is often called *toxic behavior*. In a nutshell, online interactions are different than in the real world: Many of the social cues and hierarchies that dictate decorum are not present online. These different norms, for example, asynchronous communication and anonymity, are thought to reduce the typical social barriers against abusive behavior via a phenomenon known as toxic disinhibition. That is, when online, we are more willing to behave like jerks. When coupled with a competitive environment, e.g., eSports and other competitive multiplayer video games, this often results in outlandish behavior that would be completely unacceptable in face-to-face interactions. Understanding, detecting, and combating toxic behavior is a challenging task; however, there have been some noteworthy developments in the past few years.

Understanding Toxic Behavior

Toxic behavior is a complex subject. It became a part of the general gaming lexicon in large part due to MOBAs. The authors of (Kwak et al. 2015) analyzed almost 11 million reports of 1.4 million alleged toxic players from six million matches of League of Legends. They found statistically significant difference between how different cultures ("Western" vs. "Eastern") recognized and punished toxic behavior. In particular, they noted that Eastern cultures were much more likely to punish players that harmed their own team, whereas Western players were more likely to punish toxic players that attacked other players.



Player Abusive Behavior Detection, Fig. 1 The percentage of reports for behavior that directly affects the result of the match for each region that results in a punishment

Figure 1 shows the percentage of reports for toxic behavior that might directly affect the outcome of the match, broken down by how many instances resulted in punishment per region. An explanation for this observation is that Eastern cultures are "collectivist," i.e., behavior that directly caused harm to the team is anathema while being tolerant of abuse targeted at poorly performing players.

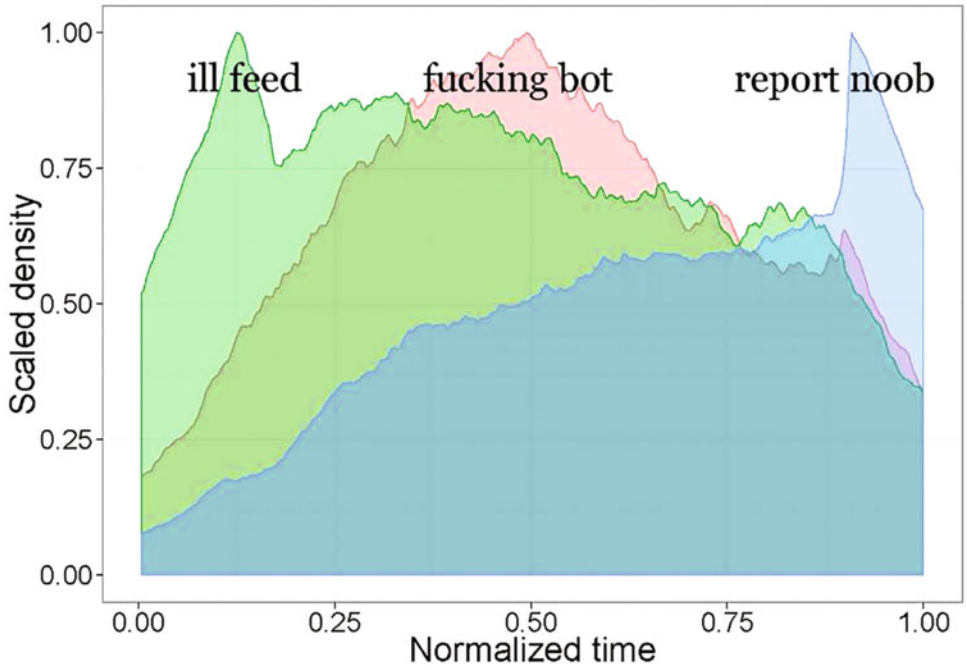
Detecting Toxic Behavior

The most common way of dealing with toxic behavior is the use of player-driven report systems and manual review. Report systems usually come into play after a match has been completed, where players are given the option of reporting another player for toxic behavior. Typically, players are given several categories to report the behavior under, as well as an optional text field to supply any additional details. Report systems are useful in that they allow players that directly experienced the toxic behavior to provide context for game developer support staff. Unfortunately, they rely on players to take the initiative, and as indicated by Kwak et al. (2015), the majority of players do not report toxic behavior in matches where it was later deemed to be present. This is likely due to the *bystander effect,* which is humans' tendency to assume someone else will help. Interestingly, however, Kwak et al. (2015) also found that explicit pleas for other players to report seemed to break through the bystander effect, resulting in an increased number of reports. The major downside to report systems, however, is that they require a lot of human effort for game developers. Invalid reports must be filtered, and human intervention is expensive and time consuming; ideally, automated systems can help out in this respect.

When it comes to automated detection toxic behavior, there are two general approaches: (1) use *domain-specific* techniques and (2) use more *generalizable* techniques.

Domain-specific techniques are those that take into account features that are specific to a particular game or genre. For example, toxic behavior in MOBAs often takes form as intentional feeding, i.e., a player deliberately dying to the enemy team which confers an immense advantage due to the in-game economy. An automated detection mechanism might aim to discover disproportionate kill/death/assist ratios, or even go so far as to detect deliberate in-game movements indicative of intentional feeding (e.g., the toxic player running in a straight line at the enemy team).

Generalized techniques aim to extract features that are common across all games. The primary example of a generalized technique uses chat logs,



Player Abusive Behavior Detection, Fig. 2 Early-, mid-, and late-game bigrams used by toxic players in the League of Legends, normalized over the length of a match

probably the most common manifestation of toxic behavior. Here, recent advances in natural language processing can be used, but even simple techniques have proven to be effective.

One of the earliest attempts to build an automated system for detecting toxic behavior made use of both techniques. The authors of (Blackburn and Kwak 2014) built a classifier to automatically detect toxic behavior in League of Legends. They extracted a variety of both domain-specific and generalized features and used a random forest classifier to determine whether players were guilty or innocent of toxic behavior. In the end, they were able to distinguish between guilty and innocent players about 90% of the time and found that even simple features extracted from chat logs (e.g., the valance or "goodness" of in-game chat) were effective. Unsurprisingly, they found that a model built on North American dataset and applied to European data was much better than random, but weaker, primarily due to reduced effectiveness of the chat-based portion of the classifier.

Conclusion

Toxic disinhibition is an unfortunate reality of online interactions. However, just like cheating, toxic behavior can be addressed. Research indicates that there are regional differences in how toxic behavior is viewed expressed, and thus developers should consider tuning their systems to the demographics of their players. Further, the efficacy of report systems might be increased by simple UI changes prompting players to report toxic behavior. Next, developers should explore their data and consider the salient features specific to their game.

Finally, while simple natural language-processing techniques can be somewhat effective, recent advances in machine learning in conjunction with domain-specific knowledge might be leveraged to produce more robust systems. The valance score used in Blackburn and Kwak (2014) is, like many sentiment scores, derived in part from a *dictionary* of words; thus, many toxic words in gaming, e.g., "noob," remain unscored.

However, recurrent neural networks (Serra et al. 2017) have been shown effective in learning out-of-vocabulary (i.e., unknown) words in the context of hate speech. Further, text-based detection can be combined with domain-specific information to further increase effectiveness. Consider Fig. 2, which plots occurrences of bigrams used by toxic League of Legends players as a match progresses (Kwak and Blackburn 2014). MOBAs like League of Legends tend to have early-, mid-, and late-game phases, and certain phrases are associated with certain points in the match. Combining advanced natural language processing while taking domain-specific information into account (e.g., the relative state of a match) is likely to greatly enhance any automated detection system.

Definition

Player Experience (PX) is a part of Games User Research where player experiences are studied to develop better interactions with games (L. E. Nacke et al. 2009a). The domain is the science of measuring user experiences for interactive entertainment – digital games being the prime focus (L. Nacke 2009a). It is proposed as a successor of User experience (UX) in HCI (Wiemeyer et al. 2016).

Introduction

PX considers games as a special software (Wiemeyer et al. 2016) and analyzes the quality of interactions of players with it. The domain focuses on the psychological, physiological (L. Nacke 2009a; L. E. Nacke et al. 2009a; Cowley et al. 2014), cognitive (Abeele et al. 2016; Järvinen 2008), emotional (Järvinen 2008), aesthetic (Sharp and Thomas 2019), and affective (L. Nacke 2009b) aspects of player

interaction within the games (Wiemeyer et al. 2016; Järvinen 2008). The primary goal is to measure PX along these aspects, and each of these aspects encompass multiple concepts within it. For example, flow is a concept of a psychological state that a player experiences while playing a game. The concept is measured using specific dimensions using a questionnaire. Player experience is thus multidisciplinary. Despite acknowledgment of its multidisciplinarity, there has not been a sufficient explication of concepts within the umbrella of PX Research in a larger context.

This article lists the constituent concepts of Player Experience and explains their contribution in studying Player Experience within the context of game studies. To understand what player experiences are, it is necessary to establish connections with influential psychological and affective concepts. The section on "Concepts Related to Player Experiences" enumerates influential work on such concepts. It is followed by research in games literature to achieve desired player experience by operationalizing those concepts and problems of such approaches. This article highlights the position of fun in the domain of player experiences and game studies. It concludes with future directions for Player Experience research, with emphasis on design research as a potential contributor to the domain of player experience.

Concepts Related to Player Experience

Player Experience research exists on a spectrum, where on one end, player experiences are analyzed from psychological and physiological perspectives. Thereby, the interactions of a player within the games are studied. On the other end of the spectrum, player experiences are analyzed with respect to the design of games. Both ends of the spectrum are analytical; they analyze player experience for different purposes. The section describes concepts from domains such as psychology, aesthetics, theory of emotions, etc., which have been applied to games and players' experiences.

Engagement

Every game strives for player engagement. It is considered as an indicator of a gameplay experience. As conceptualized by Brockmeyer, Fox, and Curtiss, a player engages with gameplay via the game software (Brockmyer et al. 2009). Similarly, Whitton considers engagement as an individual's interaction with an activity at a specific time, this engagement is not an activity but an interaction (Whitton 2011). Since players interact with gameplay via the 'special' software and engagement is not an activity but an interaction with the activity, Engagement in the domain of player experience considers engagement of a player with the software and not the gameplay. This concept can be broadened to engagement through gameplays, with adequate research.

Brockmeyer conceptualizes engagement in relation to flow, immersion, presence, and psychological absorption (Brockmyer et al. 2009). Psychological absorption is an important dimension to their questionnaire (Brockmyer et al. 2009). Psychological absorption is different from the states of flow and immersion. While flow is an autotelic state where an individual loses the sense of consciousness, absorption creates an altered state of consciousness, where affect is not accessible to the consciousness. The psychological absorption feels like "highway hypnosis" where the driver can be in an altered state of consciousness yet "manoeuvring responsibilities continue to be executed" (Brockmyer et al. 2009).

Flow

The concept of flow has been extensively used in studying player experiences. Conceptualized by Csikszentmihalyi, flow is an autotelic state that an individual experiences while performing an intrinsically motivating task (Csikszentmihalyi 1985; Nakamura and Csikszentmihalyi 2014; Csikszentmihalyi et al. 1990; Sherry 2004). The state has been characterized by: Increased and focused attention on the current activity, merging of action and awareness, loss of reflective self-consciousness, sense of control over one's actions, distortion of time experience, and experience of the activity as intrinsically rewarding. Although players of a game experience a flow

state, bridging work to analyze flow within player states needs further research.

Flow has been mapped to games elements from the literature in the Gameflow Model (Sweetser and Wyeth 2005a, b). This model provides eight dimensions offered by a game that puts the player in a flow state: Concentration, Challenge, Player skills, Control, Clear Goals, Feedback, Immersion, Social interaction. However, the model does not suggest means to design for flow (Sweetser and Wyeth 2005b). The concept of Flow has also been adapted to different categories of purposeful games as well. Dual Flow Model applies the concept of Flow to exergames and provides criteria for making attractive and effective gameplay in exergames (Sinclair, Hingston, and Masek 2009). The ARCS model for gameful learning uses dimensions of flow to improve attention, provide relevant learning content, and imbibe confidence in learners (Keller 1987). Thus, providing satisfaction to the learning experience.

The concept of flow has also been compared with the concept of enjoyment in some domains; however, there is a difference between the two concepts. Considering games as a medium that provides flow, other properties of media like Presence also become contributing factors to the state of flow.

Presence

There are several definitions of Presence which contest or compliment each other. Hence, it is best to understand Presence in terms of its conceptualizations. Presence is conceptualized in Media studies in six different ways (Lombard and Ditton 2006). In a general sense, presence is considered as a property of a medium. In this sense, a telephone can provide a lesser presence than a video conference. Of the six conceptualizations, Presence as Immersion is widely explored in the literature of PX. Although other conceptualizations are applicable to PX, Presence as immersion and Presence as transportation are explored in this article.

Presence as immersion is manifested in two ways: perceptual immersion (submergence of perceptual senses of the interactant by the media, as it happens in a VR experience) and psychological immersion (submergence via engrossment and engagement, like reading a book). Presence transports the interactants of the medium to a different place. Lombard and Ditton conceptualize transportation through presence as "you are there" where the subject is sent to an event or the object, "it is here" where the object or event is brought to the subject, and "we are together" where there is a shared reality between two interactants. This conceptualization is called Presence as Transportation.

The conceptualizations of Presence are applicable to media in general and provide some explications to characterize Presence offered by the medium. Better presence in media is characterized in terms of form variables (form of the medium), content variables (content offered by the medium) and media user variables (usage of the medium by interactant). Considering games as interactive media, Ermi and Mayra propose an immersion model for video games according to which, immersion in the game can be challenge based, sensory based, and imagination based (Ermi and Mayra). Immersion is provided by the rules, story, space, and interface of the game. However, it does not describe the constituents or means of achieving immersion or how to design for player immersion.

In addition to the concepts constituting player experience, some concepts that are treated as rewards are also important. Players essentially play games for intangible rewards, such hedonic pleasures like enjoyment and fun. Such concepts are significant for player experience.

Enjoyment

Enjoyment is equated with flow in sports psychology (Kimiecik and Harris 1996). Sociologists also explain enjoyment as an optimal psychological state. They characterize enjoyment as a psychological process that creates a positive experience. Enjoyment differs from the flow state as enjoyment can be achieved from extrinsically motivated activities (Podilchak 1991a, b). However, enjoyment is achieved only when flow is achieved (Kimiecik and Harris 1996). In this way enjoyment can be a motivator to enter the flow state.

Enjoyment in leisure studies is explained as a self-referential state where an individual experiences positive affect (Podilchak 1991a, b). According to Kelly, enjoyment is not socially or emotionally interactive and is primarily self-referential (vide, (Podilchak 1991a)). When a person is enjoying herself she sees herself in leisure or play (self-referential). On the contrary, fun is interactional, social and other-referential (vide (Podilchak 1991b)).

Fun

A player reaps fun while and after playing a game. However, it is not considered as a part of player experience frameworks and is often overlooked. The generality and lay usage of the word 'fun' adds to the difficulty of studying it from a measurement viewpoint.

Several overarching theories describing fun have been developed. Falstein brings in the evolutionary viewpoints to study fun ("Gamasutra – Natural Funativity" 2019). The emphasize that fun is not a by-product, but has evolutionary roots. He classifies fun into three parts – Physical fun, Mental fun, and Social fun. Fun is given an evolutionary purpose through this viewpoint. Anyone who enjoys developing survival skills is having fun. In this sense, a physical activity that enhances our survival instincts is condensed into Physical fun. Examples like exploration activities, use of tools, hunting are still found in present-day video games. Through Social fun, members of primitive society put their efforts to look out for each other. These efforts are manifested in forms of gossip, social gatherings, and now in present-day video games in the form of clans and communications in Massively Multiplayer Online Games (MMOGs). To achieve Physical and Social fun, players manipulate patterns of entities around us. This is defined as Mental fun. In this way, fun helps in learning new skills that are essential for survival. Ralph Koster establishes a similar line of thought. A game becomes boring (or not fun), when it stops offering new learning experiences and feels repetitive (Koster 2013).

Bogost describes fun in novelty and proposes that it is achieved by the act of reframing reality (Bogost 2016). Fun lies in transforming a reality to another reality that is unforeseen, unexpected, and novel. Fun is in finding the unfamiliar in familiar circumstances (Bogost 2016). Fun in this sense is in the act of manipulation. It is associated with processes of exploring, evaluating and presenting it to others, hence other-referential. In this sense, fun is also necessarily social (Podilchak 1991a). Such general viewpoints offer initial guidance to understand fun, but to identify dimensions of fun as an experience obtained from a gameplay, a more specific viewpoint with games in focus is needed.

John Sharp and David Thomas consider fun as an experience – "Fun describes the experience of a person playfully engaging with a situation or object" (Sharp and Thomas 2019). They consider play as the process of obtaining such an experience and extend the study of player experiences to the medium that provides such an experience. They refer to the domain as aesthetics of games.

Broad concepts like flow, fun, engagement, et cetera offer only some guidance to analyze games. These concepts are operationalized and measured through diverse approaches.

Operationalizing Concepts of Player Experience

Larger concepts are operationalized using smaller measurable concepts. Such a process is domain specific. Flow has been operationalized via Gameflow model in games and ARCS model in the domain of learning. In addition to operationalizations mentioned in the previous section, some concepts do not use established psychological or affective theories, but they take the empirical approach to create newer frameworks of player experiences.

The aesthetic part of the MDA framework focuses on the specific concepts to create player experiences and provides a list of eight components offered by the game (Hunicke et al. 2004). Similarly, GameFlow applies the concept of flow to come up with specific concepts for games (Sweetser and Wyeth 2005a). Another set of specific concepts has been provided by questionnaire-based measurements of player

experience – Game Experience Questionnaire (GEQ) (Denisova et al. 2016; IJsselsteijn et al. 2013), Player Experience of Need Satisfaction (PENS) (Denisova et al. 2016; Deci and Ryan 2012), Playful experience questionnaire (PLEXQ) (Boberg et al. 2015). Player experiences are studied in specific contexts like learning (ARCS) (Keller 1987), exergames (Sinclair et al. 2009) that provide us with domain specific elements of player experiences. Table 1 provides a list of specific concepts of the listed frameworks.

These frameworks and models rely on the measured aspects of player experience – psychological and physiological. The dimensions of these questionnaires help in analyzing player experience through self-reporting and affective ludology provides guidance in measuring the psycho-physiological variables of players to gauge player experience (L. Nacke 2009a). But the effects are not attributed to the design of the game. For example, the concept of flow is viewing at player experiences, but it is too general and "too vague for a detailed analysis of the game" (Järvinen 2007, 2008) Flow is a state of the player and not of a game ("Rules of Play: Game Design Fundamentals – Katie Salen, Katie Salen Tekinbaş, Eric Zimmerman – Google Books" n.d.). Its derivatives like the GameFlow model also help in measuring player experiences, but do not guide in designing those experiences (Sweetser and Wyeth 2005b). A detailed analysis of player experiences should either answer questions like why a player accepts challenges voluntarily? or should identify which features of a game system offer a particular experience?

Player Experience, Design and Research, Table 1 List of specific concepts associated with measurement of player experiences

Framework	Specific concepts
MDA	Sensation, Fantasy, Narrative, Fellowship, Challenge, Discovery, Expression, and Submission
GameFlow	Concentration, Challenge, Player skills, Control, Clear Goals, Feedback, Immersion, Social interaction
Patterns of flow	Challenging task balanced with skills, Path to more challenges, Feedback from the environment
Questionnaire	**Questionnaire**
GEQ	Competence, Sensory and Imaginative immersion, Flow, Tension, Annoyance, Challenge, Negative Affect and Positive Affect
PENS / SDT Approach	Autonomy, Competence, Relatedness, Presence, Intuitive Control
PLEXQ	Captivation, Challenges, Competition, Completion, Control, Cruelty, Discovery, Exploration, Expression, Fellowship, Humor, Nurture, Relaxation, ensation, Subversion, Suffering, Thrill
Context specific frameworks	**Specific concepts**
ARCS player experience for games	Attention, Relevance, Confidence, Satisfaction
Dual Flow Model	Attractiveness, Effectiveness

There are two shortcomings of current player experience research: (1) The analytical approaches consider games as a black box or a software to interact with. These analytical frameworks are not linked to the areas of games design (PPAX author). The psychological, physiological, emotive, affective, and cognitive dimensions of player experiences are measured and evaluated, but the design drivers of these dimensions have not been identified (Järvinen 2008). In other words, the analysis does not guide in the design of the games. (2) Current PX research does not engage with the notion of fun, despite being the central purpose of games.

Player Experience Design

Design research is oriented toward "finding the ultimate particular". It binds the general to specific through a common language (William and Alexander 2017). Player Experience research focuses on analysis, measurement aspects of the game experiences, while Applied Ludology attempts to provide this common language between player experience research and games design (Järvinen 2008). Applied Ludology provides ways to embody psychological variables in

the game states, thus providing an applicable theory to design for specific player experiences. Still, the domain of Applied Ludology poses the question – What are some design drivers affecting the emotional states through game events?(Järvinen 2008) How are those states formed from a given rule set? This is where Player experience design ought to operate. In this sense, player experience design should focus on the specific designable game elements that create desired game events and thus design better game experiences.

Player Modeling

► Game Player Modeling

Player Personas and Game Choice

Jukka Vahlo and Aki Koponen
School of Economics, University of Turku, Turku, Finland

Synonyms

Gameplay preference categories; Player profiles; Player types; Player typologies

Definition

Player personas are representations of player profile types, based on identified patterns in gameplay type preferences, motivations to play, or player behavior data. Player personas are constructed to support player-centric game design and targeted marketing.

Introduction

Since the early 1980s, categorizing video game preferences has been a sustaining topic in game research and game design literature. However, during the past 10 years, both mobile and non-mobile marketplaces have saturated, and the need for developing advanced player typologies for targeted marketing has become even more striking.

Consequently, many game companies lean today toward player-centric game development, which requires knowledge of the intended player audience and tools for identifying their representative player types or *player personas*. Determining the target audience impacts game design and monetization models, but it requires also a deep understanding of players' preferences and motivations to play (Adams 2014, pp. 32, 134–135). A core task for player profiling models is to aid game companies to design games with better market fit and to give tools for the players for discovering games that suit best their personal needs and thus to support their *game choice*.

This chapter explores prominent ways to identify player personas based on players' gameplay type preferences. After introducing approaches on profiling players in player type research, the chapter demonstrates empirically the role of gameplay preferences in game choice while taking into account both motivation to play and preferences for gameplay challenges.

Overview: Research on Player Types

Player type models can be distinguished from each other by identifying their main research

question. Models which study player behavior ask *how the player plays a game* and what kind of *play style* players adopt or prefer. Motivations to play and other psychographic approaches such as adaptations of the uses and gratification paradigm examine *why the player plays games* in general. Recently, another approach has been introduced for studying *what kinds of games players prefer* to play. These latter models argue that players can be profiled based on their preferences in gameplay types which arguably predicts their *game choice* (Vahlo et al. 2017). The fourth and final main approach on player types aims to identify *what kind of gaming mode*, gaming mentality, or game intensity a player exemplifies – e.g., if she could be described as a casual player, a social player, a hardcore player, or a competitive player (see, e.g., Ip and Jacobs 2005; Stewart 2011; Kallio et al. 2011; Deterding 2013).

Furthermore, some approaches focus on investigating players' personality types by applying existing psychological theories of personality and combining that with, e.g., player behavior data (e.g., Lankveld et al. 2011; McMahon et al. 2012) or survey data (e.g., Teng 2008; Jeng and Teng 2008; Braun et al. 2016). These studies ask *what kind of personalities distinctive player types have*. In a sense, these models are second-order approaches on player types since they investigate the correlations between two existing branches of research: personality types and player types.

Player typologies can be approached from the perspective of segmentation and marketing theory (Hamari and Tuunanen 2014) or by making a distinction between player profiling and player modeling. *Player modeling* designates scrutinizing patterns of dynamic interaction in ongoing gameplay. *Player profiling* is based on analyzing information that cannot be reduced to gameplay but which refers instead to players' sustaining game preferences, motivations, and, e.g., cultural background. (Yannakakis et al. 2013; Cowley and Charles 2016) Player modeling is congenial with player behavior studies, whereas player profiling points toward models of gameplay type preference and motivations to play. The concept of "persona" has been utilized in player modeling studies in the task of recognizing consistent patterns of archetypical play styles (Tychsen and Canossa 2008; see Cooper 2007).

The most well-known behavioral player type model was fashioned by Richard Bartle (1996, 2003). Bartle's model was based on analyzing several hundred bulletin board postings by MUD (multiuser dungeon) users and classifying their preferred playing styles into four player types of *achievers*, *explorers*, *socializers*, and *killers*. Regardless of the fact that the model was based on players' preferred play styles in MUDs and it was not intended as a general model, it has been widely used in game development for two decades.

Player behavior models (e.g., Bartle 1996, 2003; Drachen et al. 2009; Mulligan and Patrovsky 2003; Tseng 2010; Stewart 2011; Bean and Groth-Marnat 2016) are useful for understanding how players play the game they have already chosen to play and what kinds of temporary or more constant play styles can be identified by behavioral profiling (Pirker et al. 2016). Thus player behavior models offer data for improving retention and monetization of a given game. However, it is difficult to make general conclusions of player personas or their game choices beyond the preselected game of which data (e.g., telemetric data, game logs) is being analyzed.

Bartle's (1996, 2003) model was also used as the starting point for a major investigation on motivations to play massively multiplayer online role-playing games (MMORPGs) by Nick Yee (2006). By conducting principal component factor analyses ($N = 3000$) on inventory of 39 items that were generated based on Bartle's (1996) four player types, Yee was able to identify ten components that further loaded on three overarching latent dimensions of *achievement*, *social interaction*, and *immersion*. Later the model was validated by conducting a confirmatory factor analysis with cross-cultural data (Yee et al. 2012).

Motivations to play models aim to flesh out the reasons why people play games in general or, e.g., online games or mobile games in particular. These models, as well as player *personality type* approaches, are often based on existing psychological theories including Myers–Briggs Type

Player Personas and Game Choice, Table 1 Four primary approaches of video game player type research

Model	Core research question	References	Model emphasis
Gaming intensity	*What* is the preferred gaming mode?	Kallio et al. (2011)	Player profiling
Motivations to play	*Why* do we play games?	Yee (2006)	Player profiling
Gameplay type preferences	*Which* games we choose to play?	Vahlo et al. (2017)	Player profiling/ player modeling
Player behavior	*How* we choose to play a game?	Bartle (1996)	Player modeling

Indicator (e.g., Bateman et al. 2011), Big Five (e.g., McMahon et al. 2012), HEXACO model (e.g., Worth and Book 2015), the uses and gratification paradigm (e.g., Sherry et al. 2006), or Self-Determination Theory (e.g., Ryan et al. 2006; Przybylski et al. 2010). However, psychological theories are developed to deal with general traits of human psychology – not with situational behavior such as gaming. Motivations to play models may not provide much information of what kind of games people prefer to play or what play styles they are likely to adopt, and thus these models can be difficult to utilize in game development.

Both player behavior models and motivations to play models can be argued to be limited in the objectives of profiling players' gameplay type preferences and predicting players' game choice. Recently, two models have been developed for this purpose (Vahlo et al. 2017; Tondello et al. 2017). Vahlo et al. (2017) presented an approach based on identifying recurrent game dynamics, i.e., patterns of interrelated game mechanics as they emerge in ongoing gameplay, of contemporary video games ($N = 700$). After identifying 33 core game dynamics types, they fashioned a survey for 1,718 participants from Finland and Denmark (age 18–70) in which the participants' preferences in each of the 33 game dynamics were enquired. An exploratory factor analysis revealed five factors of game dynamics preferences, namely, *assault*, *manage*, *journey*, *coordinate*, and *care*. The authors conducted a cluster analysis based on respondents' factor scores, i.e., like/dislike of the five game dynamics factors, and identified a total of seven player types or personas of *the mercenary*, *the companion*, *the adventurer*, *the commander*, *the patterner*, *the explorer*, and *the daredevil* (Table 1).

Vahlo et al. (2017) and Tondello et al. (2017) both argue that focusing on game dynamics or gameplay activity types fills a gap in current player type research since this approach makes it possible to combine the elements of games with players' preference profiles. Arguably, this posits gameplay type preferences as a tool for both profiling players into player personas and predicting their game choice. The gameplay type approach is congenial with media choice theory and especially with structuration theoretical models which argue that dynamical and structural characteristics of game media constitute an important factor in identifying media choice and, consequently, game choice (Webster 2009).

Empirical Demonstration: Gameplay Type Preferences and Game Choice

Gameplay can be defined as the interaction between the challenges the player faces and as the actions the player is allowed to take to overcome the challenges in a fictional setting (Adams 2014, p. 9). Gameplay of a game does not, however, consist only of types of gameplay challenges and fictionality. The player tries to overcome the challenges in gameplay activities, i.e., game dynamics, such as exploring the gameworld, managing cities, shooting enemies, piloting vehicles, or taking care of farms (see Vahlo et al. 2017; Vahlo 2017). It can be offered, therefore, that gameplay type preferences can be broken down into three dimensions of challenges, activities, and fictionality (e.g., narrative, theme, and

aesthetics) and that these three dimensions can be appropriated as a basis for constructing player personas to predict game choice. Following Adams (2014), challenges and activities are considered here to form the core of player–game interaction.

In gameplay, the player may come across with, e.g., tactical challenges, challenge pattern recognition, logical challenges, challenges of memory and knowledge, or challenges of physical coordination (Adams 2014). The challenges are dealt with by engaging in distinctive types of gameplay activities. For instance, a player may have to coordinate her physical movement in activities of dancing, sneaking, or jumping on platforms. It is plausible also to assume that a person who decides to play has some kind of *motivationa*l driver to do so. Indeed, the question of how distinctive forms of goal-directed activities in gameplay relate with psychological need satisfaction has also been studied in prior game research (see e.g., Bostan 2009).

This section presents an empirical demonstration, which was designed to investigate how being motivated to play, enjoying gameplay challenge types, and appreciating gameplay activity types predict game choice. A total of 3551 survey respondents were obtained in 2016–2017 from Canada ($N = 1364$), Japan ($N = 1270$), and Finland ($N = 917$) to construct representative samples from the three countries. The surveys were made in cooperation with a market research company by using a web-based tool. The age of the participants ranged from 18 to 60 years. In the beginning of these surveys, the respondents were enquired to report on a Likert-5 scale how interested they were in digital games (1 = not at all, 5 = very interested). If a respondent reported to have no interest in video games at all, he or she was then instructed to quit the survey.

The surveys included a 25-item motivations to play inventory (Likert-5, 1 = completely unimportant, 5 = very important), 9-item gameplay challenge preference inventory (Likert-5, 1 = very unpleasant, 5 = very pleasant), and a 52-item gameplay activity preference inventory (Likert-5, 1 = very unpleasant, 5 = very pleasant), where the latter was based on the model by Vahlo et al. (2017). Respondents' habits of playing digital games of a total of 17 distinctive genres were enquired by asking how much they played games of each genre (Likert-5, 1 = not at all, 5 = very much).

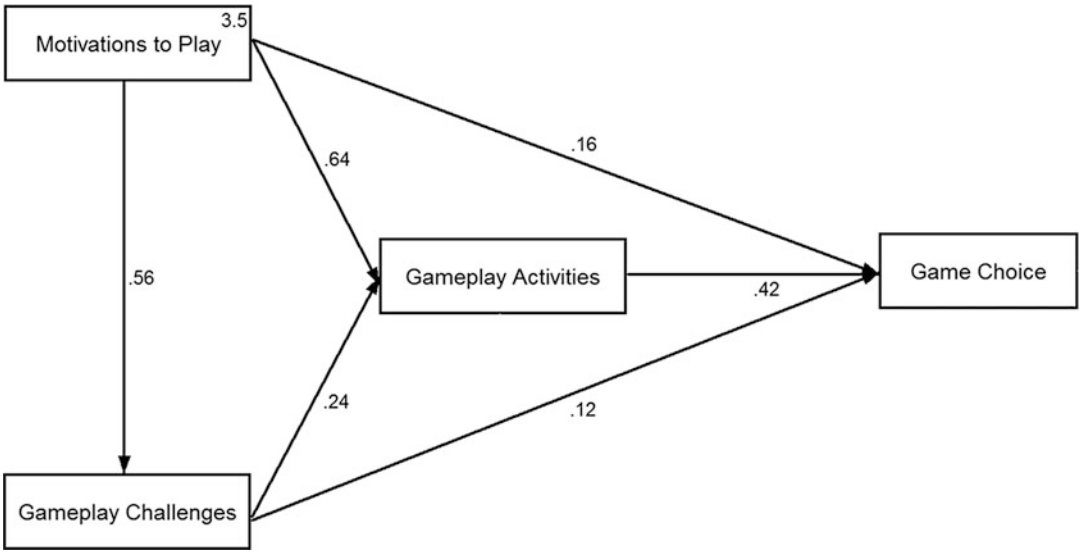
A structural equation model (SEM, Stata 14.2) was constructed for investigating how being motivated to play, enjoying gameplay challenge types, and appreciating gameplay activity types predicted respondents' habits of playing games of the variety of genres. The measurement model is presented in Fig. 1.

The indirect, direct, and total effects for the model (Fig. 1) were estimated by using maximum likelihood method. In the data of 3551 respondents, being motivated to play was the main predictor of playing games of all genres (0.55). However, the effect of being motivated on the game choice was largely *indirect* (0.39). Gameplay type appreciation had the second largest total effect on playing games of all genres (0.42), and it had clearly the strongest *direct effect* on playing games of varied genres. Gameplay challenge preference had only weak (0.22) total effect on the game choice, and both its indirect (0.10) and direct (0.12) effects can be considered very weak.

Based on these results, it can be offered that motivations to play, gameplay challenge preference, and gameplay type appreciation are all significant factors in predicting game choice. Although being motivated has the largest total effect on playing games of varied genres, gameplay appreciation has much more relevant direct effect on game choice. Since motivation has only weak *direct* effect on game choice, it is plausible to suggest that constructing player personas on game choice can be primarily based on players' gameplay type appreciation and secondarily on their gameplay challenge preferences.

Conclusion and Discussion

This chapter provided an overview of prominent approaches to player type research and player



Player Personas and Game Choice, Fig. 1 A game choice prediction model reporting standardized effects of motivation, challenge preference, and gameplay type appreciation on playing video game genres ($N = 3551$). All reported effects are significant on the level of $p < 0.001$

profiling. It pinpointed qualitative differences between the four approaches of motivations to play, player behavior, gaming intensity, and gameplay type preferences. All of these approaches can be used to construct personas, i.e., representative players, for the developer and marketing.

The chapter demonstrated empirically a structural model predicting game choice based on motivations to play, challenges, and gameplay activities. Based on the empirical demonstration, one can argue that for business purposes player personas based on gameplay activity preferences are the most promising and yet underutilized at the moment.

Demonstration showed that one approach is not adequate. All the factors have an impact on game choice, and therefore businesses should seek to have wider understanding of the whole phenomenon. More data should be collected to understand better media consumption and purchase behavior. One solution for that task could be developing AI-based engine for generating personalized game recommendations for distinctive player segments and simultaneously collecting data concerning persona responses to different marketing methods.

Player-Avatar Link: Interdisciplinary Embodiment Perspectives

Nina Rosa, Wolfgang Hürst, Remco Veltkamp and Peter Werkhoven
Utrecht Center for Game Research, Utrecht University, Utrecht, The Netherlands

Synonyms

Bodily presence in digital games; Embodiment in digital games; Player-avatar relation

Definitions

Player-avatar link: experience of embodiment by the player, caused by the extension of the player's perception and agency through the avatar into the digital game world.

Introduction

In digital games research, the concept of the avatar is a much discussed topic. Many works have been dedicated to understanding every aspect of this phenomenon, ranging from the origin of the term all the way to its functioning as a game component (see Juul and Klevjer 2016 for a brief overview of key discussions). Once the aspect of the player is addressed, one of the most intriguing issues become the link between the player and the avatar they control. Why is it, for example, that players become distressed when they see their avatar in danger? And why do they refer to it as "I"? While it is widely acknowledged that some type of link indeed exists, there is still much disagreement on what the nature of this link actually is. This entry discusses the different embodiment perspectives of the player-avatar link. Specifically, we first examine phenomenological accounts of player embodiment in games from a Humanities background, and then investigate the sense of embodiment in virtual media from a Natural Sciences background.

Terminology

A few concise definitions are provided as a starting point for the main discussion. These definitions are simplified versions of what they may represent within different disciplines.

Avatar – The object over which the player can assert control.
Character – The figure that exists in the meaningful game world, including any form of backstory and personality.
Embodiment – The process of adjusting one's internal body representation to the current circumstances.
Player embodiment – The experience that the avatar has changed the internal body representation and phenomenal body of the player.
Presence – The experience of being present to something.
Spatial presence – The experience of being present in a certain environment.
Immersion – The technological quality with respect to sensorial information.

In the following, the term "game figure" is used to refer to either avatar and/or character, when it is not specified by the author(s) of the cited article.

Perspectives Within the Humanities

In the Humanities there are several authors who acknowledge that the player-avatar link is exactly embodiment, in the form of extension of the player's body. In a number of his works, Wilhelmsson has argued that many aspects of a game experience are consequences of a Game Ego manifestation (Wilhelmsson 2001, 2006, 2008).

The Game Ego is a bodily based function that enacts a point of being within the game environment through a tactile motor/kinesthetic link. This means that the player's sensory system is extended to the game environment, and the Game Ego becomes another body and/or an extension of the body. The consequences include identifying with the manifestation and more generally allowing the player to experience the game's narrative elements, and as a result evoking emotional responses and the experience of presence. Klevjer states that there is a paradoxical prosthetic relationship between player and avatar (Klevjer 2006, 2012). By applying Merleau-Ponty's philosophy on the body's duality (Merleau-Ponty 1945), it is argued that video games allow the player to relocate their intention for actions (as a subject) into screen space, while at the same time a proxy (as an object) exists in the game. Crick also draws upon Merleau-Ponty's reasoning to explain how the game can be perceived as another physical world during play (Crick 2010). That is, the player exists in two worlds and operates both on and in the game. It is emphasized that the video game experience must be of embodied perception, since we still require our body (and the combination of all senses) to perceive it, and it in turn affects our bodily state. The controller used by the player allows agency in the game world and can become an extension of our body through habit; the avatar's movement is incorporated within the player's body schema and becomes an extension of the bodily basis of consciousness. Lastly, Vella argues that, indeed, the player may embody the avatar and achieve a subject position in the game world, but as a character the game figure still has an autonomous identity that can be acted out (Vella 2013). Therefore, the act of avatar-play constitutes the enactment (or performance) of a character.

These works so far demonstrate an emphasis toward the roles of perception and cognition in embodiment: their combined impact on our experience of the real world is considered in the experience of game worlds. Farrow and Iacovides claim that exactly such reasoning is just one step too far (Farrow and Iacovides 2014) and describe three inconsistencies with respect to human embodiment aspects laid out by Merleau-Ponty. Firstly, on a physical level bodies within game worlds cannot conform to real world duality (e.g., tactile and pain), and we do not relate to bodies in virtual worlds in the same way that we do in the real world. Secondly, on an intentional level a player experiences the game as convincing when there is a sense of nonmediation, which is something only "invisible" game control systems can achieve. Lastly, on a worldliness level it is possible that game worlds only become meaningful through play with other humans. Together, this leads to a limit to the degree of digital embodiment.

There are also authors that explain that embodiment in games is not "simply" a process of perception. For example, Newman has argued that "video games are not interactive, or even ergodic," since they do not consist of continuous play and even have integral parts that are nonergodic (Newman 2002). Here, ergodicity refers to the definition by Aarseth: a user must use (active) effort in order to experience the medium (Aarseth 1997). Moreover, there is a level of ergodicity in noncontrolling players (active spectators), which indicates that feelings of immersion, engagement, and being-in-the-game are separated from an interface-level control loop. During play, the degree to which the player embodies the game figure is not dependent on representation, since it is merely seen as a set of capabilities: it is equipment to be used by the player.

A last group of authors agree that the player-avatar link takes on more forms than just embodiment and that this is very related to different types of play. Linderoth demonstrated how children frame the game figures during certain moments of gameplay, which leads to three different functions of game figures (Linderoth 2005): they can become roles for socio-dramatic interaction, tools as extensions of the player agency, and props for self-presentation in the presence of others. Similarly, Bayliss argues there are three positions of game figure play: playing through (the avatar is equipment), playing as (sometimes character, sometimes avatar), and playing with the game figure (play with the game rather than play the game) (Bayliss 2007). The game figure embodies the intentions of the player as their avatar, and its limitations with respect to functionality

simultaneously constitute it as an embodied character. It is highlighted that any sense of being-in-the-game-world relies on attitude of the player with respect to the three positions of play, and not the video game itself or the technological platform. Lastly, Banks found that players' motivation and attitude toward play went hand in hand with the social role the game figure fulfilled in the relation with the player (Banks 2015). From unsocial to social, the relations were game figure as object, as me, as symbiote, and as social other.

To summarize, there is a substantial group of authors that argues for embodiment of the player as a result of a perceptual link: the player's body is extended into the game through the avatar. However, others argue that real world embodiment assumptions cannot simply be translated to assumptions for the game world and that the function of the game figure depends on the type of gameplay, which in turn depends on the player's attitude toward the game.

Perspectives Within the Natural Sciences

In the Natural Sciences, there is little attention to the player-avatar link in games specifically; however, there are many works that discuss how the body schema can be changed by virtual bodies in, for example, virtual reality (VR). This corpus is a result of empirical studies in cognitive neuroscience on the more general experience of being connected to a body. Although there are many concepts that are part of this experience, there are three in particular that have gained a great deal of attention, that together form the sense of embodiment: body ownership (the sensation of owning a body), agency (the sensation of controlling a body), and self-location (the sensation that the locations of you and your body coincide in space) (Kilteni et al. 2012a; Longo et al. 2008). Here, spatial presence differs from self-location since the former concerns the relation between the self and the body, and the latter the self and the environment. A classic experiment to assess ownership over a limb is the rubber hand illusion (Botvinick and Cohen 1998). In this experiment, the rubber hand is stroked either synchronously or asynchronously with the real hand, which is out of sight. Synchronous feedback evokes a sense of ownership over the rubber hand, while asynchronous feedback diminishes it. With similar setups for not just limbs, but also entire bodies (i.e., the body transfer illusion), various studies have assessed the importance of seemingly relevant factors to the illusion, such as synchronous visual–tactile and visual–motor feedback (Tsakiris et al. 2006), viewing perspective (Petkova and Ehrsson 2008) and congruent body alignment and connectivity (Perez-Marcos et al. 2012). It has also become apparent what the roles of agency and self-location are in this regard (Kalckert and Ehrsson 2012; Maselli and Slater 2014; Tsakiris et al. 2006).

Using VR it became possible to inspect real-world factors that could not, or with much difficulty, be studied otherwise. Lugrin et al. examined the body transfer illusion during a full-body touch-the-target task in VR, where ownership over humanoid, robot, and block avatars were compared (Lugrin et al. 2015). They found that there was no difference in ownership levels between the different avatars (the actual levels are not provided); however, the humanoid avatar caused the participants to experience having two bodies to a higher degree than the other non-humanoid avatars. The authors believe that this effect was related to the so-called uncanny valley effect. Besides full-body illusions, the extension and addition of body parts has also been examined. For example, Kilteni et al. examined how the degree of ownership over a virtual arm depended on elongation of the arm and found that with visual–tactile feedback the breaking point was four times arm's length (Kilteni et al. 2012b). Regarding supernumerary limbs, Steptoe et al. showed that participants could experience ownership and agency over a humanoid avatar with a long tail, while also performing better in a full body touch-the-target task when the tail could be controlled by hip movement than when it moved at random (Steptoe et al. 2013). In a similar study, Stevenson Won et al. compared performance in an armbased touch-the-target task between a humanoid avatar and one with an extra arm protruding from the chest, which could be controlled by wrist rotations (Stevenson Won et al. 2015). For targets outside of the normal arm's reach, but in reach of

the additional arm, participants performed significantly better with the extended body than with the normal body. Interestingly, the measured levels of presence were low overall and did not differ between conditions. The authors explain that the low results could have occurred because participants were so involved with controlling the avatar in order to complete the task, making them less aware of the virtual surroundings. This is in contrast to many works in Natural Sciences that agree that there is in fact a positive relation between presence and task performance (an elaborate discussion can be found in Nash et al. 2000).

Although measuring embodiment in games directly (i.e., through ownership, agency, and self-location) is uncommon, there have been many works that measure presence and/or immersion in games for a variety of purposes. For example, in a series of studies, Weibel and Wissmath studied possible influences and effect of spatial presence and flow in a variety of games using both factor analysis and path analysis on questionnaire results (Weibel and Wissmath 2011). Firstly, they found that spatial presence and flow are separate constructs and that flow in turn consists of two subcomponents: absorption into the experience and smoothness of the experience. Secondly, they found that a participant's motivation generally influences flow, whereas a participant's immersive tendencies generally influence presence. Lastly, flow directly influenced enjoyment and performance of each game, whereas presence only did this indirectly through flow.

Besides subjective qualities of gameplay, objective qualities have also been examined. For example, Hou et al. studied players' immersive tendencies as a precondition of presence experience, and screen size as a media form variable (Hou et al. 2012). By analysis of questionnaire results they found that a larger screen had a positive effect on game figure evaluation, player mood, and both spatial and self-presence (i.e., when a player experiences that the avatar is him-/herself), but no difference in enjoyment. Also, immersive tendencies moderated the effect of screen size on presence, but not of the other game evaluation aspects. In particular, enjoyment was not affected, in contrast to the study by Weibel and Wissmath.

To summarize, although there is little research on the player-avatar link itself, there is an immense corpus of literature regarding the general experience of being connected to a body in reality and VR that prominently argue from a perception background: multimodal feedback can cause participant's to experience other (virtual) bodies as their own. There have also been studies that empirically show that a player's immersive tendencies are an important determining factor of the experience of spatial presence in games.

Body and Environment

Although the different disciplines study the same problem very differently, there are a few interesting similarities between the two, specifically regarding their interpretation of the problem. For example, both disciplines agree that during gameplay the player's internal body representation changes. In Humanities, some authors draw upon the phenomenology of (natural) perception and argue that a part of the player must be represented in the game. In Natural Sciences, the reasoning is that if extra bodies (or body parts) are presented correctly, then they can be accepted by the player as belonging to them. Both sides argue for an extension of the player's body, and many results support this claim: players frequently refer to the avatar as "I," react emotionally and physiologically to avatar events as if it is their real body (Armel and Ramachandran 2003), while still experiencing ownership over their actual real bodies (Guterstam et al. 2011).

Another similarity is the important role of the experience of the game environment, in particular what the determining factor is of this experience. In computer science, it was until recently quite acceptable to regard presence as a consequence of a system's immersive and interactive capacities (and of nothing else). This is often a crude operationalization of Steuer's model on presence in VR (Steuer 1992); the statement concerning varying individual experiences of presence due to, for example, differences in the content is frequently ignored. Currently, a progressively growing number of studies are demonstrating the importance of the player's immersive tendencies

to the experience of the environment. In game studies, system-versus-narrative discussions are nothing new: Is the experience of spatial presence (or being-in-the-game-world) a result of the vividness and interactivity of the system, or is this a result of the environment becoming meaningful through narrative? There are numerous authors that are inclined toward the latter (Bayliss 2007; Farrow and Iacovides 2014), although undoubtedly the answer is partially both. A possible reason for the exclusion of this view in computer science is one of pragmatic nature: there is not yet an existing measure for "the degree of narrative." This is absolutely logical when looking at the complexity of the matter; the experience of narrative can differ per person, per experience of gameplay, time of day, and so on, but that does not mean it is nonexistent.

For research in both disciplines, the experiences of self, body, and environment often go hand in hand. In many cases, it seems to (roughly) come down to two aspects: the role of mediation and the role of immersive tendencies. That is, the only way a person could experience a mediated situation as real is if the input is *realistic* (or convincing) enough, and if they allow themselves to *pretend* the experience is not mediated. It is not apparent what the interdependence is between these two aspects, nor whether they are of equal importance: acceptance in the second aspect allows experience of the first on the one hand, but it may very well be that if the first occurs perfectly then the second happens automatically (as suggested in Wilhelmsson 2008).

Conclusion

This entry has provided an interdisciplinary discussion of the player-avatar link. For Humanities we see that there is no consensus on the importance of perception over player attitude and narrative. In Natural Sciences, the experience of changing the body schema through perception is prominent; however, there is recently also noticeable focus on personal characteristics that might underlie the experience in the first place. Both disciplines are inclined to argue about the experiences of both body and environment and end up at the same important question: What are the roles of mediation and immersive tendencies in these experiences? In this sense, while the initial analysis from both disciplines seemed contradictory, one could say that for this particular problem the focus in both disciplines is converging, creating a interesting future research opportunity for interdisciplinary research in this area.

Plug-in-Based Asset Compiler Architecture

Nicusor Nedelcu

Build toolchain; Data baking; Data compiler; Data cooking; Data processor

Definition

A plug-in-based asset compiling solution for game development where each plug-in handles a data file format and outputs an optimized form for a specific hardware/software platform.

From the beginning of the game creation process to the end, development revolves around two main subjects: code and data (game art and other type of assets). In the past, data was formatted specifically for the one platform the game was about to run on. Now we have to format the same data for many different platforms. In order to satisfy this new requirement, we need access to source assets that can be compiled into a variety of targets. More work has to be done, since special care has to be taken for each format.

However, there are ways to reduce the pain involved in this more complex pipeline. To make this process as streamlined as possible, a plug-in-based asset compiler that can load converter plug-ins for the given asset types, is proposed. The plug-in-based nature of the compiler can also help developers create their own plug-ins for any other special asset types they need. In this entry, I describe how to set up and code such a compiler using the example of a texture converter/compiler plug-in. The platform we are going to use is Windows and the language is C++, with few modifications regarding the OS specifics, the code should work on other environments or even adapted to other languages.

Design

The underlying plug-in loading system can be a "traditional" dynamic link library (DLL) loading and querying for the proper interfaces. We will be using the Windows dynamic link library API, but the code is almost the same for other operating systems. The DLL can export a special function that will return an instance of the converter interface (see Listing 1). The same goes for other platforms (OS/X, Linux), using their specific dynamic link library API implementations.

Listing 1. Creating the asset converter instance using the exported DLL function

```
DLL_EXPORT AssetConverter*
createAssetConverter();
```

The interface of the asset converter would look like Listing 2.

Listing 2. The asset converter interface

```
class AssetConverter
{
public:
enum EType
{
eType_Unknown = 0,
eType_Compiler = 0>>1,
eType_Importer = 1>>1,
eType_ImporterCompiler
= (eType_Compiler | eType_Importer)
};

AssetConverter(){}
virtual ~AssetConverter(){};
virtual bool convert(const char*
pSrcFilename, const char* pDestPath,
const Args& rArgs) = 0; // Args class
is a command line argument parser, not
shown here. Basically holds a list of
arguments and their values
virtual const char* supportedExtensions
() const = 0;
virtual EType type() const = 0;
};
```

The asset converter has a type that represents what the converter does with the given input file:

compiles or converts. We make this distinction between compilers and converters because we would like to use compilers to compile data from our intermediate format to the final platform-optimized format and converters to convert from third party formats to our intermediate format. An example compiler would be: cube.json (the intermediate format) to cube.mesh (final optimized format) or an example converter: cube.fbx to cube.json.

We can also have a compiler and a converter in one implementation (flag eType_Importer-Compiler) that can handle third party and intermediate formats (for example, a TextureConverter that converts third party JPG/PNGs and compiles to a custom format like.TEX).

The convert method is the one called by the asset compiler executable when the given command line arguments are passed to it and they match the file extensions returned by the supportedExtensions() method. This function should return something like a file mask such as *.jpg, *.tga, *.png, or *.texture, so even a simple substring matching test can select the right converter(s).

The command line arguments are shared for all the converters; each one can pick up its own arguments and their values.

By convention, the converters will be called first on the given assets, and after that we will call the compilers. Since we (probably) generated/converted assets from the previous step, now we can compile those intermediate formats into final binary optimized ones for specific platforms.

The main asset compiler executable will load all plug-in DLLs from either a specific folder or the same folder as the executable. We can use any kind of plug-in loading scheme. For example, we can have those DLLs with their extensions named. plugin,.converter, etc. In this way, we dynamically load only the eligible ones, skipping the unsupported/unknown DLLs.

Once a plug-in is loaded, we retrieve the address of the DLL exported createAssetConverter() function and instantiate the converter. Then, with all plug-ins loaded, we match each input asset filename with the return string of the supportedExtensions() of each converter. If the match is true, then we call the converter to take care of that file type. After that we can continue to pass the filename to be handled by other matching converters, or we could come up with a stop boolean return value so the file will be handled only once by a single converter and not by further matching converters if the return value is false. Even further, we could have some sort of dependency tree, when converters would be called after others have finished converting assets.

Obviously, another thing that speeds up the compilation/conversion process is multithreading. In a first phase, we can schedule groups of files to be converted on separate threads. Then, when we convert a few files, the converters could spawn several threads to take care of a single asset. We must be sure, however, that the available cores are used/spread evenly, whether on a CPU or GPU.

Multithreading asset compilation can be a little tricky when dependencies are involved, so for this process to be safe, and to avoid problems arising from two threads concurrently modifying the same resource, we should build a dependency tree and put each main branch and its subbranches and/or leaves on their own thread. Various methods for thread synchronization can be used, like mutexes, semaphores, each operating system having its own API for that.

The main compiler class would look like Listing 3.

Listing 3. The asset compiler class

```
class AssetCompiler
{
public:
AssetCompiler();
virtual ~AssetCompiler();

bool compile(const Args& rArgs);
void compileFolder(
AssetConverter::EType aConverterType,
const char* pMask,
const char* pExcludeMask,
const char* pCompileFolder,
const char* pDestFolder);
protected:
vector<AssetCompilerWorker>
m_workerThreads;
.....................
};
```

The main asset compiler class has the compile(. . .) method (synchronous call; it will wait until every asset compile thread finishes), which will take the actual command line arguments. The compileFolder(. . .) method (asynchronous call; it will just start the threads) will process a given folder for a specific converter type, with a filename mask, an excluding mask, the actual compile folder, and destination folder for the output files. The class also has some worker threads for multithreaded processing of the input assets.

Example

We can show, for example, a texture converter/compiler plug-in. The code could look like Listing 4.

Listing 4. The texture converter and compiler

```
class TextureConverter : public
AssetConverter
{
public:
TextureConverter();
~TextureConverter();

bool convert(const char*
pSrcFilename, const char*
pDestPath, const Args& rArgs);
const char* supportedExtensions()
const
{
return "*.jpg *.png *.psd *.tex";
}
EType type() const
{
return eType_ImporterCompiler;
}
};
```

The texture converter plug-in class will return all supported file extensions and its type, so the main compiler class will select it when appropriate.

Inside the convert method, the code will check the input filename and dispatch the logic to the specific image format handler.

This class can reside in a DLL, which contains a single converter, but one can also have as many converter classes in a DLL as it is needed. In that case, the query function will just have to change to support multiple classes. See Listing 5.

Listing 5. A plug-in with multiple converter classes inside a single DLL

```
// this class must be implemented by
the plug-ins
class AssetCompilerPlugin
{
virtual int getClassCount() = 0;
virtual AssetConverter*
newClassInstance(int aIndex) = 0;
}
DLL_EXPORT AssetCompilerPlugin*
createPluginInstance();
```

The exported createPluginInstance() will create the plug-in's class instance, which will take care of instantiating converter classes.

Other converter plug-in examples include an FBX converter, mesh compiler, prefab compiler, shader compiler, MP3/OGG/WAV converter, level compiler, etc. The plug-in system can be developed further with class descriptors, such that information can be retrieved about the converter classes without having to instantiate them unless they are needed.

Conclusion

Making the asset compiler modularized can yield huge benefits: shorter development time, the ability to extend and debug the tool, and happy third party developers, who will use the tools since they can implement new converters/compilers for their custom data file formats.

Keep in mind optimizations like multithreading; dependency trees; CUDA/GPGPU operations to speed things; a CRC-based last-modified file info database so we can skip assets that have not changed; and even safely running many compiler executables on the same data folders.

The solution can be implemented in various ways. The converter ecosystem can be detailed as needed so it will fit perfectly into the game engine's pipeline.

Poisson-Disk Sampling: Theory and Applications

Tong Wang
Cygames, Inc., Tokyo, Japan

Synonyms

Blue noise sampling; Poisson-disk sampling

Definitions

The Poisson-disk sampling is a sampling strategy or process that will ensure each sample to be independent to each other with a certain random distribution, while keep a certain minimum distance r from each other.

Introduction

Sampling has a crucial importance in computer graphics theory and applications. The digital system of a computer will need effective and high-quality sampling algorithms to convert continuous-time signals to discrete-time signals while preserving as many details as possible. A good sampling algorithm will dramatically increase the efficiency and quality of many computer graphics applications such as texturing, object placements, remeshing, and rendering. Figure 1 shows two different sampling patterns.

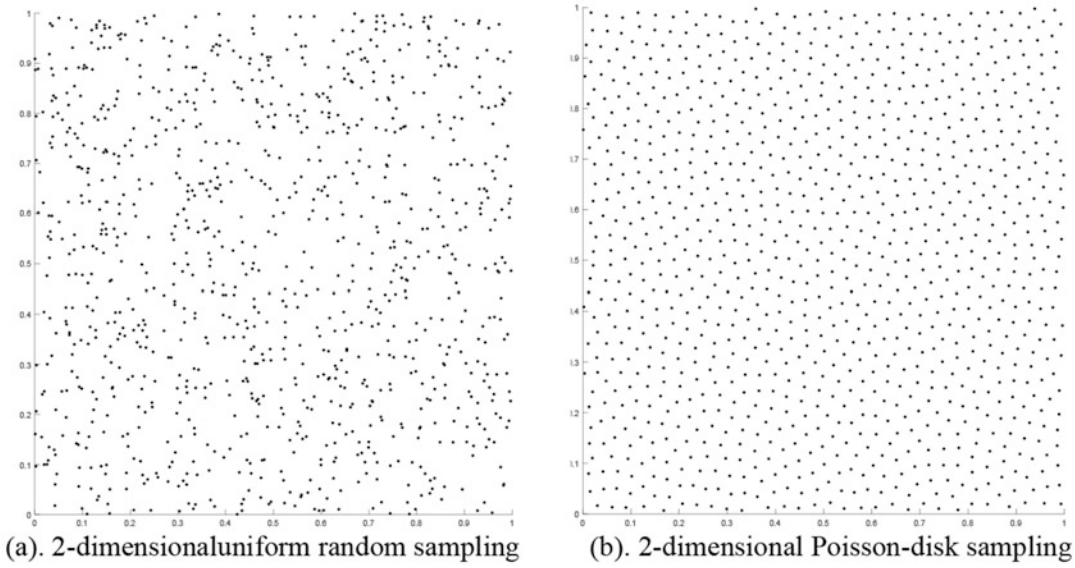
The problem with uniform random sampling in the 2D spatial domain is that it will introduce variance that can cause high-frequency noise in some applications. A uniform random sampling will leave gaps and clusters in the sample domain. In the gap area, underlying information cannot be efficiently evaluated, while in the cluster area redundant evaluation will harm the efficiency of the application.

To solve such a problem, we need to introduce samples that have both unbiased randomness in the distribution, while scattering in the sampling domain with low variance and discrepancy. **Poisson-disk sampling** is the most popular sampling strategy that can generate such evenly distributed samples with unbiased randomness. A broader concept of such an ideal sampling pattern that has unbiased randomness with evenly scattered samples is called **blue noise sampling**. Figure 2 will show problems of uniform sampling and how the Poisson-disk sampling pattern can help to solve such problems.

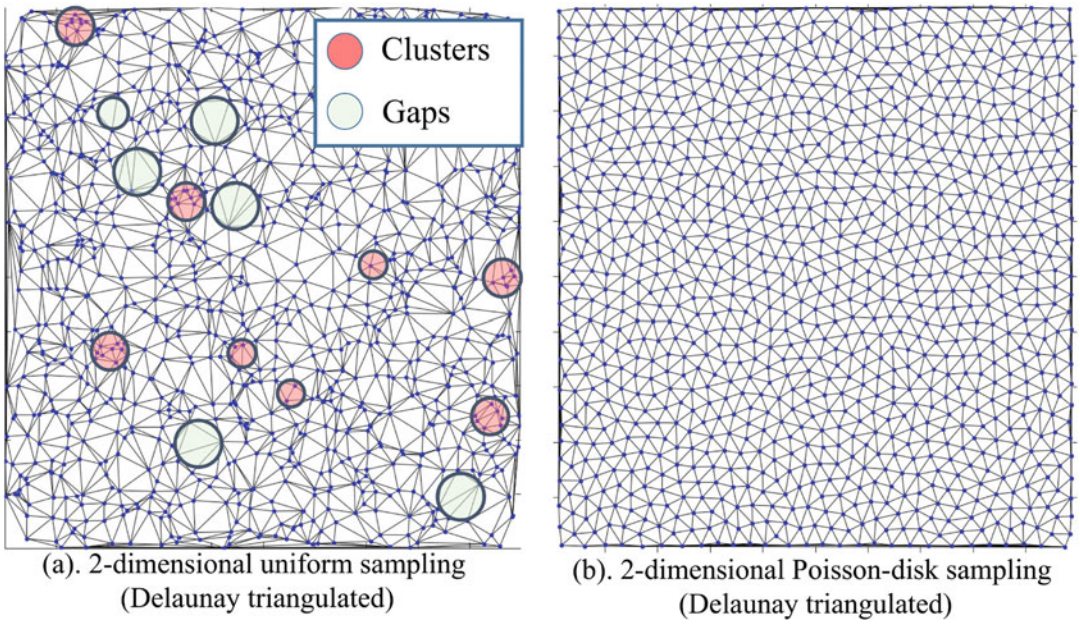
The Poisson-disk sampling distribution is a sampling strategy that will ensure each sample to be independent to each other with a certain random distribution, while also keep a certain minimum distance r from each other. Cook (1986) is one of the earliest works that presented Poisson-disk sampling as a proven pattern for antialiasing. It is proved that Poisson-disk sampling is capable of generating high-quality geometry and image quality in other applications such as remeshing and image synthesis as well.

Evaluation of Samples

It is common to use the **power spectrum** to analyze the features and quality of a sample set. The



Poisson-Disk Sampling: Theory and Applications, Fig. 1 (**a**) 1024 2D random sampling pattern with uniform distribution and (**b**) 1024 Poisson-disk samples in 2D space (Note the differences between different sampling strategies)



Poisson-Disk Sampling: Theory and Applications, Fig. 2 (**a**) Delaunay triangulation of 1024 uniform random samples in 2D space, notice the gaps and clusters that will harm the quality of the samples and (**b**) 1024 Poisson-disk samples in 2D space, which is randomly distributed while evenly scattered

method is introduced by Ulichney (1988) and was discussed in detail by Lagae and Dutre (2008). The use of the power spectrum in sample analysis is often called spectral analysis. We also use the formulation in Lagae and Dutre (2008) and present the N samples as sums of δ functions (x_k represents a sample in the d-dimensional sampling domain):

$$S(\mathbf{x}) = \frac{1}{N}\sum_{k=1}^{N}\delta(\mathbf{x}-\mathbf{x_k}) \tag{1}$$

Thus, the Fourier transform of this function is:

$$f(\mathbf{w}) = \int_D f(\mathbf{x})e^{-2\pi i(\mathbf{w}\cdot\mathbf{x})}d\mathbf{x} \tag{2}$$

$$S(\mathbf{x}) = \frac{1}{N}\sum_{k=1}^{N}e^{-2\pi i(\mathbf{w}\cdot\mathbf{x})} \tag{3}$$

Then we can calculate the power spectrum $\mathcal{P}$ as an important measure of a sample pattern:

$$\mathcal{P} = \left|\sum_{k=1}^{N}e^{-2\pi i(\mathbf{w}\cdot\mathbf{x})}\right| \tag{4}$$

Take 2D samples as an example: the 2D samples will be translated into a 2D power spectrum. A uniform random example will have a constant spectrum while a good sampling pattern will contain less low-frequency energy which is beneficial for most applications. See Fig. 3 for more explanations of the power spectrum and it is radial average as a 1-d measurement.

Poisson-Disk Sampling: Generation

Dart-Throwing

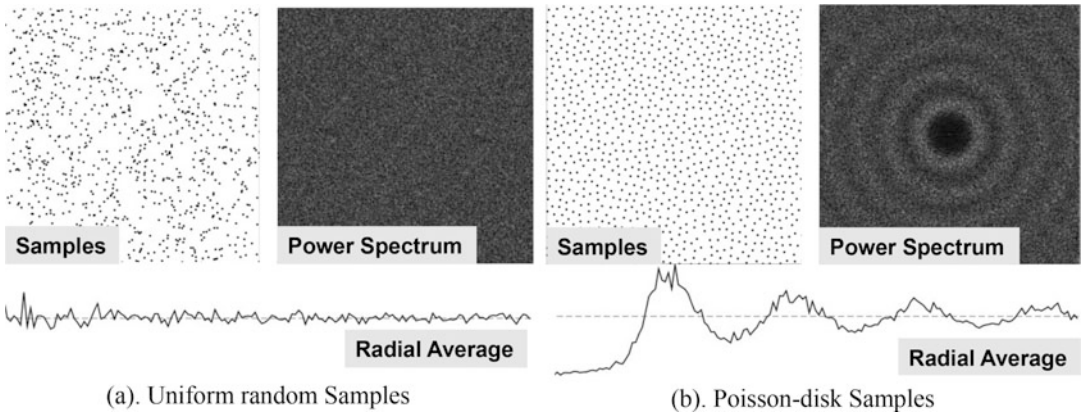
The most fundamental algorithm to generate a Poisson-disk sample pattern in arbitrary dimension is called **Dark-Throw** algorithm as introduced in (Dippé and Wold 1985) and (Cook 1986). The process of the algorithm to generate a Poisson-disk sampling with a conflict radius r is:

1. Throw a d-dimensional sample *dart* into the domain
2. Accept the *dart* if it's not within radius r
3. Reject the sample if it is within radius r from any other sample
4. Repeat the process until no samples will be accepted

There is an obvious problem with the naive dart-throw strategy: the convergence of such an algorithm is very difficult. The rejection rate will increase dramatically as more and more space is occupied by other samples. There are several variations in dealing with such performance issues to make the sampling time reasonable.

Variations of Dart-Throwing

There are some early works that try to split the space and manage gaps explicitly in order to



Poisson-Disk Sampling: Theory and Applications, Fig. 3 (**a**) The power spectrum of a uniform random sample is white noise and the radial average only contain constant or DC(direct current) information, and (**b**) the power spectrum of Poisson-disk samples will have such "ring" effects with low DC in low frequency area and high DC in high frequency area

increase the acceptance rate of insertion. A thorough survey of the earlier dart-throwing based method is in Lagae and Dutre (2008).

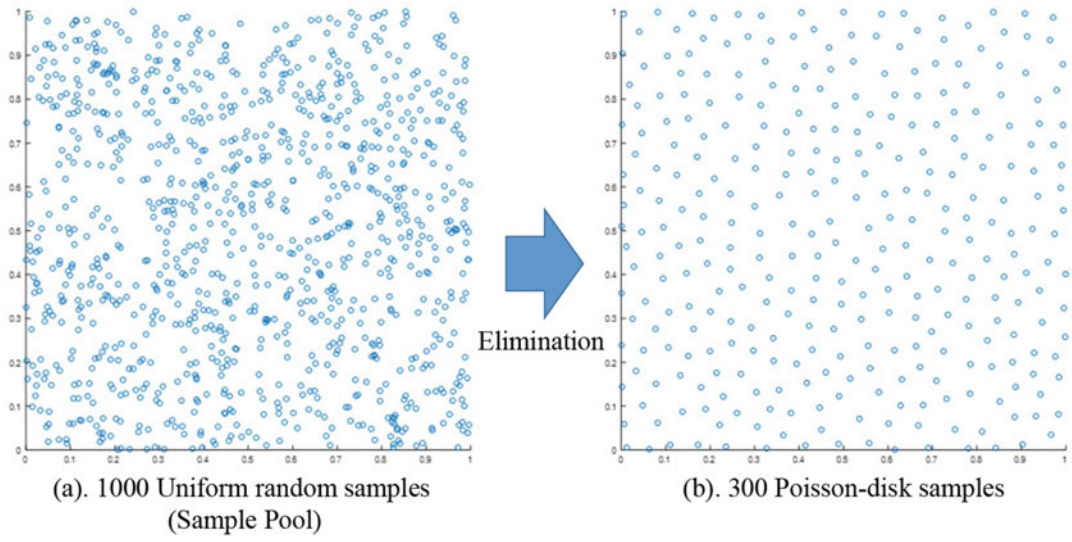
There are methods that try to manage explicit gaps more efficiently. Ebeida et al. (2011) proposed an efficient Poisson-disk sampling algorithm that will ensure maximal coverage, which means that no further sample can be inserted without violating the conflict rule. The work from the same author Ebeida et al. (2012) is a more elegant algorithm that manages active gaps in a quad-tree or high dimensional spatial subdivision data structures, which is much easier to construct and maintain. A more specific study on gap management is conducted by Yan and Wonka (2013), who analyzed the gap-related concepts in such a family of Poisson-disk sample generation algorithms and provided a more general framework for gap management techniques.

Gap management aims to reduce the rejection rate in the sampling, while the parallelization of Poisson-disk sampling algorithms will increase performance in the actual implementation of such algorithms on parallel computing models, such as multicore CPUs or GPU with massive SIMD (single instruction, multiple data) execution hardware. For example, Wei (2008) tries to split the space into different phase groups and define parallelism by the number of threads that can throw dart samples in each phase group. Bowers et al. (2010) improved such a parallel scheme to sampling on 2D manifold surfaces.

Sample Elimination

The traditional dart-throwing and its variation mainly focused on reducing the rejection rate, but the elimination based algorithm will reduce the number of samples with a certain strategy until the rest samples satisfy the Poisson-disk sampling rule. Figure 4 shows how a dense uniform sample is converted to a sparse Poisson-disk sample set through an elimination process. The weight-based elimination methods developed by Yuksel (2015) is one of the most simple and elegant algorithms.

Here we will briefly discuss the main idea of a weight-based elimination algorithm. Suppose the target sampling count is N, the elimination-based method will first generate kN (empirically k will be larger than ten) uniform random samples in the sampling domain (high dimensional Euclidean space or manifold space), then calculate a *weight*



Poisson-Disk Sampling: Theory and Applications, Fig. 4 (**a**) 1000 uniform samples and (**b**) Eliminate 700 samples from the uniform random samples with a certain rule (e.g., weight-based elimination), the 300 samples left will appear to be Poisson-disk sampling pattern

parameter for each sample by how close its neighbors are. Samples will then be organized in a priority queue by the weight parameters. Samples with higher weight will be eliminated from the set. Each elimination will cause several updates of weights in the priority queue. The elimination will go on until the target sample count N is reached.

Ying et al. (2013) further discussed parallel elimination by defining how the explicit phase group subdivision can be re-interpreted as intrinsic parallelism that used a unique priority number for each sample to automatically form the recursive independent subsets in the sampling process.

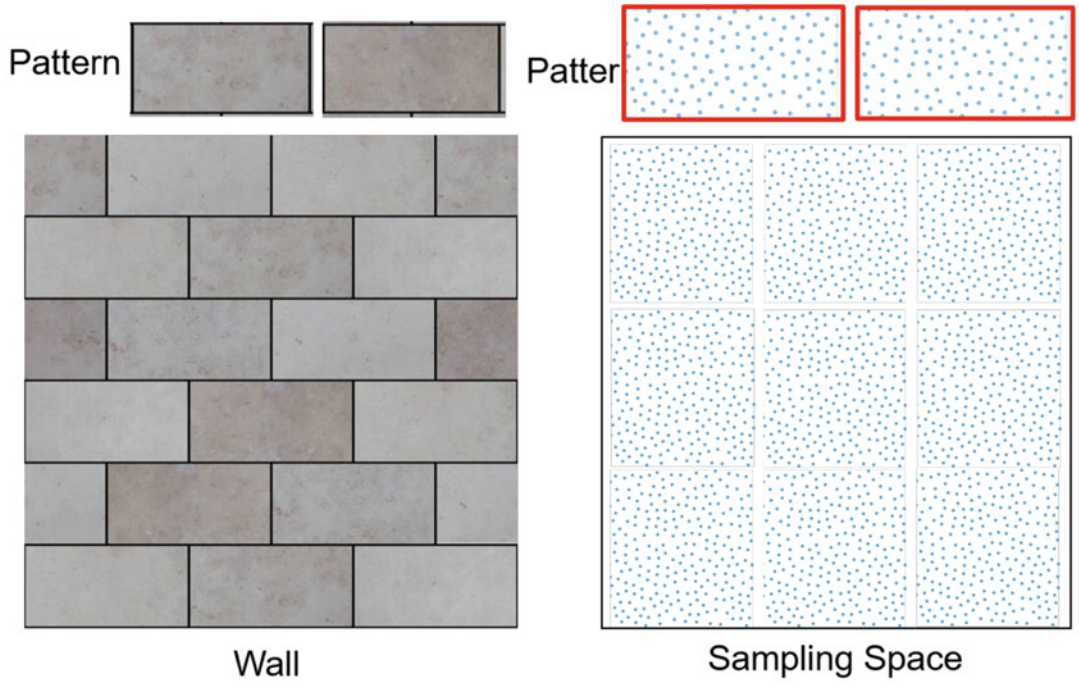
Tile-Based Methods

Another approach to efficiently generate Poisson-disk samples is by tile-based methods. Several tiles filled with Poisson-disk samples will be pre-generated and they will be used as a construction unit to generate larger sample sets by tiling the sample tiles in the sampling domain. Figure 5 is a simple illustration of how tile-based methods work.

Cohen et al. (2003) is an early pioneer work in tile-based Poisson-disk sampling. The use of recursive Wang tile in Kopf et al. (2006) significantly increased the sampling rate while still be able to control the bias and aliasing. Lagae and Dutré (2005) developed a texture basis function that enables the real-time generation of an infinite amount of Poisson-disk distributions of arbitrary size through tiling.

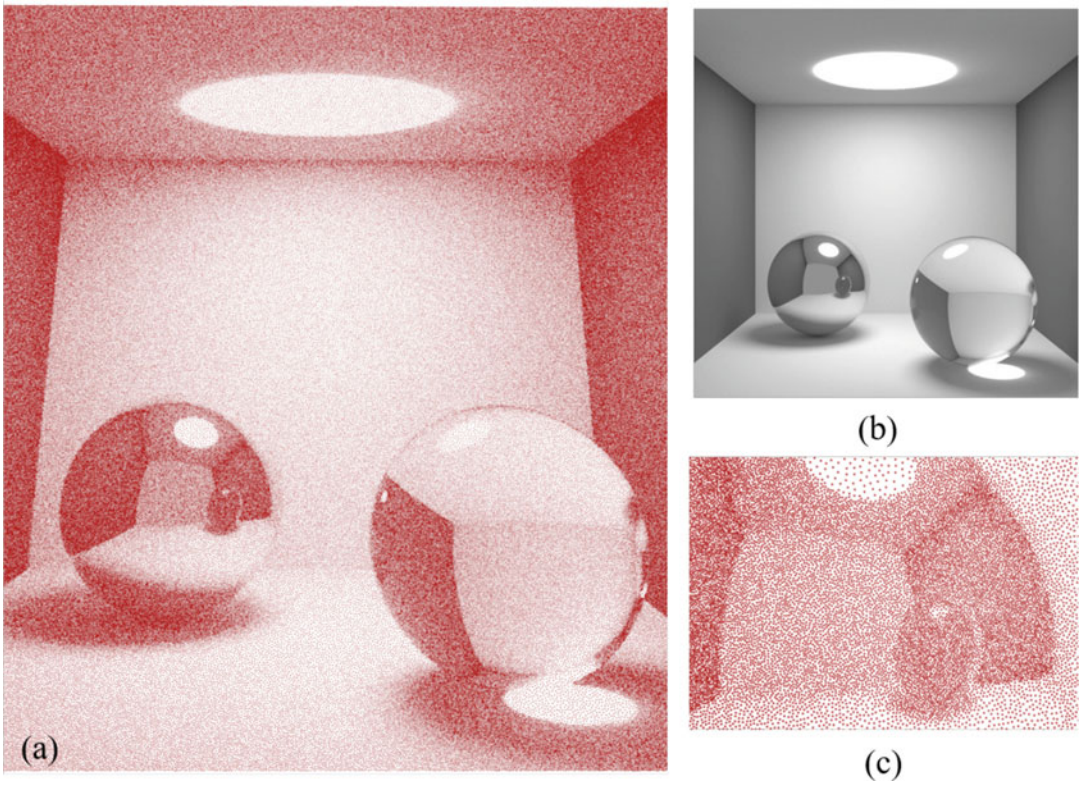
Applications

As a well-known stochastic sampling strategy, Poisson-disk sampling performs well in many applications in computer graphics related fields. It is proved that the blue-noise sampling pattern (which means sample patterns with low DC energy during low frequency and high DC energy during high-frequency domain in the power

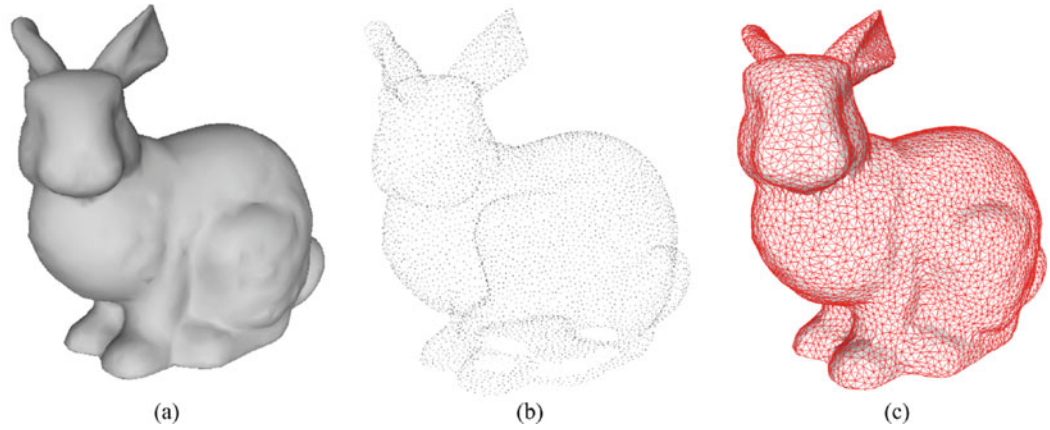


Poisson-Disk Sampling: Theory and Applications, Fig. 5 Basic idea of the tiling-based method. To tile a sample domain, we need to prepare the sample pattern and the tiling method, similar to the tiling process of a wall. It is important to tile in an aperiodic and random way to avoid extra aliasing and bias

Poisson-Disk Sampling: Theory and Applications, Fig. 6 Variance will be revealed as noise in human visual in rendering. A Poisson-disk sampler in (**a**) can help alleviate variance problem from a uniform random sampler in (**b**)s Killeroo model courtesy of headus/Rezard



Poisson-Disk Sampling: Theory and Applications, Fig. 7 (**a**) is the stippling result. Note how Poisson-disk samples with different density is shading the image, and (**b**) is the original black and white image. (**c**) is the enlarged local feature



Poisson-Disk Sampling: Theory and Applications, Fig. 8 (**a**) shows the surface of the famous model Stanford bunny, and (**b**) is a set of Poisson-disk samples on the surfaces. These samples will then be triangulated with algorithms such as ball pivot base reconstruction to form a mesh with better statistics as is shown in (**c**)

spectrum graph) will have a low discrepancy, while still keep good randomness to help avoid aliasing and bias. Here we will give a simple introduction of how Poisson-disk sampling patterns can be beneficial in various applications.

Rendering

Poisson-disk sampling patterns perform well in antialiasing thanks to the low discrepancy and high randomness feature. Figure 6 shows some examples and comparisons of using Poisson-disk samples in various stages during the pipeline of off-line rendering.

Image Stippling

Image stippling is an application that creates image shading only with small dots. The variation of density of dots will represent different colors of the image. Image stippling can be performed using varied radius Poisson-disk samples, which means that for each sample, the conflict radius can be different according to a weight or color function assigned to it. Figure 7 is an example of stippling a rendered result in a path tracer of the famous Cornell box scene.

Remeshing

Remeshing is a set of methods to find a better discrete representation of a given surface. In many computer graphics applications, a good mesh will contain roughly equal edge length and triangle area. The Poisson-disk samples on 3D surfaces will help such a process of finding a good mesh from the underlying surface. Figure 8 shows a simple remeshing process.

Conclusion

In this entry, we introduced the basic theory and related applications of Poisson-disk sampling. We summarize three different generation techniques that can alleviate expensive dart-throwing. As one of the most important blue-noise sampling strategies, Poisson-disk sampling is widely used in various fields. Readers can check survey literature such as Yan et al. (2015) for further study.

Definition

The Pokémon World Championship (PWC) is an annual tournament for the ranked Pokémon video game qualifiers and the trading card games' best players.

The Pokémon Trading Card Game (TCG) is a collectible card game based on the Pokémon franchise by Nintendo.

The Pokémon Video Game Championships (VGC) are a series of tournaments worldwide for Pokémon players to complete for prizes.

Introduction

The Pokémon World Championship debuted in 2004 for the trading card game and it quickly grew in popularity with the inclusion of the video game series in 2009. The championship is separated into three divisions based on age: Junior (ages 13 and below), Senior (ages 14–17), and Masters (ages 18 and up).

To qualify for both the Trading Card Game and Play! Pokémon divisions, you must win a certain number of *Championship Points* at Championship-sponsored events. The number of

points you need to receive is based solely on how many people are in your region and age division.

To be able to enter and earn points for these Pokémon events, you need to have a Trainer Club Account with a matched Trainer ID in order to opt in.

Nintendo Formed (1889)

Nintendo, originally known as Nintendo Koppai, debuted in Japan on September 23, 1889, as a card company. Specializing in Hanafuda Cards – a type of Japanese playing card – the creator, Fusajiro Yamauchi, believed that his company would grow quickly. He was correct. For more than 100 years, Nintendo has dabbled in taxi services, ramen noodles, and even "love" hotels. Little did he know that Nintendo would become one of the largest video game companies, with an annual gross revenue of over $10 billion.

Nintendo entered the gaming scene in 1975. In 1978, they made their first game for the computer. It was not until the 1980s when they really took off in the video game world when Shigeru Miyamoto helped with the development of Donkey Kong. This would be the beginning of many of their greatest games.

GAME FREAK Started Up (1980s)

GAME FREAK started out as a self-published gaming magazine around the 1980s by Satoshi Tajiri and Ken Sugimori, with Tajiri writing and editing, and Sugimori illustrating. On April 26, 1989, the duo started a video game company in the same name. Although their idea for Pokémon did not take off at first, they were reputable enough to get a job helping Nintendo make games by joining Namco. It was soon after the development of Mendel Palace, also known as Quinty, that they moved on to help Sony make a game called Smartball for the SNES (Super Nintendo Entertainment System). Eventually Nintendo asked for help with the game Yoshi. This game involved moving falling blocks to make familiar looking pictures of Mario enemies. After the success of this game, they continued to help Nintendo for the next few years while making the first Pokémon games on the side.

Creatures Inc. Created (1995)

Creatures Inc. was created on November 8, 1995, from the remnants of the then disbanded Ape Inc. – creators of the Earthbound/Mother series. Creatures Inc. would go on to become a big developer within the Pokémon Company. They were one of the biggest developers for the early Trading Card Game, as well as some of the merchandises. Although it was not the main focus, they also helped with a lot of the 3D modeling for some of the newer Pokémon games.

As of 2019, no one was really sure about Creatures Inc. On December 9, 2019, Creatures Inc., along with Shogakukan, were removed from GAME FREAKs list of business partners on its website. Creatures Inc.'s own website ended its timeline on March 3, 2018. What remains to be seen of this third of the Pokémon Company is yet to be seen.

Pokémon's First Game Released (1996/1998)

Pokémon's first games to release were Pokémon Red and Green. They were released in February 1996 and again in 1998 in the United States as Red and Blue. Its reception was widely popular on release, becoming one of the most bought games for Nintendo's handheld console line, the Game Boy. The premise of Red, Green, and Blue would set the mold for future games. In it, you play as a young boy named Red who is tasked with going around and filling out the Pokédex while also completing the Gym Challenge and becoming the next Pokémon Champion. While doing all these, your character – an 11-year-old boy – also takes it upon himself to help take down the Criminal Organization known as Team Rocket. With 8 Gyms, 151 Pokémon in the Pokédex to find, and countless hours of exploring, Pokémon was quickly gaining attention.

Pokémon, now household name, has had eight generations of games, as well as countless spinoff

games from the main series, such as Pokémon Snap, or Pokémon Rangers. Even though they use the same formula for most of their games, they still continue to sell over millions of copies with each release. In fact, their most recent main game release sold over 20 million units, surpassing Gold and Silver – the Gen II Pokémon games. However, the most sold Pokémon game remains to be Red/Green/Blue, with over 31.38 million units sold as of December 2020.

The Pokémon Company Launched (1998)

The Pokémon Company launched in 1998 by the trio of Pokémon creators: Nintendo Co., Ltd., GAME FREAK Inc., and Creatures Inc. It was originally named Pokémon Center Co., Ltd., but changed its name in 2000 to the Pokémon Company. They control the overall management of the Pokémon brand.

Pokémon's Trading Card Game Developed (1996/1999)

This is the beginning of the Pokémon tournament craze. The Pokémon Trading Card Game (TCG) was developed so that anyone, regardless of age, could enjoy competing with friends, family, and strangers. Beginning in 1996, 102 cards were made by the company Media Factory. Three years after their popularity took off, they were introduced to North America by Wizards of the Coast. Quickly gaining popularity, tournaments were being held, and it was a craze that many people enjoyed and still enjoy today. Whether you are a competitor in the tournaments or just a Pokémon card collector, it was apparent to many, especially the company, how quickly it would grow.

In fact, over 30 billion cards have been printed. What is even more crazy is the amount of money people will spend on cards. Some of the rarer cards would sell for thousands of dollars. This gaining popularity and willingness for people to buy cards were noticeable enough for the Pokémon Company to step in and start the world championship.

Pokémon Organized Play (2003)

Pokémon Organized Play came to be after Wizards of the Coast lost their license to the game in 2003. With this new power over the Pokémon Trading Card Game (TCG), the Pokémon Company International, aka Pokémon USA, started to organize new tournaments, leagues, and prize systems.

The Pokémon World Championship for the TCG (2004)

Although there were technically championships held before Nintendo's takeover of the TCG, the official Pokémon World Championship did not start until 2004. Between 1999 and 2001, Wizards of the Coast would hold the Tropical Mega Battle in Honolulu, Hawaii, every year until the Pokémon Company's eventual takeover of the series.

In order to enter the Pokémon World Championship, you must be chosen for the World Series by meeting a set of qualifications. These qualifications are your overall ratings (i.e., how many points you have gained throughout the season and so on) and how well you did in the previous year's tournament. You also need to have a Trainer Club Account and a paired Trainer ID in order to compete and gain points in tournaments.

The Championship is "set over three days with a last chance qualifier (known to players as The Grinder) on a Friday to fill seats left vacant for various reasons (e.g., no travel, local qualifiers) until all seats are filled. The second day is limited to Swiss Pairings over a set number of rounds, and the top players (16 each in the Junior and Senior Divisions, as well as the top 32 in the Masters division) move onto the Sunday rounds. The format for this final is single elimination, until the finals, which are a best two matches out of three to decide the World Champion," (*World Championships* n.d.). There are also age qualifiers depending on what division you can get into. These are: Junior (ages 13 and below), Senior (ages 14–17), and Masters (ages 18 and up).

PWC Includes VGC in Competition (2009)

The Pokémon World Championship (PWC) debuted in 2009 in San Diego, California. The premise of this tournament was very similar to the Pokémon Trading Card Game (TCG). The main difference is that PWC was a video game and not the card game. There was no Masters Division until 2011. Originally, it was the top 2 who would advance to the finals, but now it is the top 8.

"The most recently released Pokémon game is used for battles. The in-battle rules and banned Pokémon vary from year to year. Usually, the battles are double battles, and each player can use four Pokémon. The event format consists of Swiss rounds, followed by a single elimination tournament. In 2009, the top two advanced to play the finals on Sunday, whereas since 2010, the top eight advance to play in a head-to-head single elimination event to decide the World Champions," (*World Championships* n.d.).

Unfortunately, the 2021 championships for both the VGC and TCG were canceled due to COVID-19. However, the championships were expected to resume in the following year.

POP Changed Its Name to Play! Pokémon (2010)

In 2010, Pokémon Organized Play (POP) changed its name to Play! Pokémon. It continues to operate as the official governing body of the Pokémon Trading Card Game (TCG), the Pokémon Video Game Championships (VGC), the Pokkén Tournament Championships, and the Pokémon World Championship (PWC).

Conclusions

Having captured the hearts of many, and just giving that nostalgic feeling that anyone gets when playing a game from their childhood, Pokémon fans, TCG players, VGC players, and those who simply just like the show are overly thrilled to be celebrating 25 years of the franchise as of 2021. With every new generation, new and younger fans join the competitions, thus leading the Pokémon Company to have the luck of an ever-growing player base. It is without a doubt that Pokémon will continue to influence the game industry.

Political Game Design

Diğdem Sezen
Faculty of Communications, Istanbul University, Istanbul, Turkey

Synonyms

Activist games; Documentary games; Newsgames; Persuasive games; Serious games

Definition

Political game design the exploration of the scope, limits, and possibilities of game design for a politically motivated position. Political games may aim to inform, motivate, or challenge people about politics and let them to engage with different levels of political sphere through gameplay.

Introduction

While earlier examples can be found in the form of games designed for the education of rulers in core principles of military and politics (Von Hilgers 2012); according to Lerner the history of political games and political play can be traced back to the nineteenth century, to the invention of Prussian tabletop wargames. By 1960s mostly cooperative political minded physical games were used by activists both in the USA and in Latin America to achieve political change (Lerner 2014). Political analog games are still used in many areas including urban design and peacebuilding as a tool and a method (Tan 2014; Brynen et al. 2018). The conceptualization and practice of political video games on the other hand starts with 2000s.

Political Video Games

Since mid-2000s game scholars have been arguing for the design of video games for purposes beyond entertainment and particularly for political activism. In 2005, Gonzalo Frasca had predicted that video games "will become an increasingly popular platform for political and social commentary and activism as they become increasingly prevalent in households" (Frasca 2005). Joost Raessens argued that the use of games to foreground social and political issues by collectives of game developers, artists, and political activists would turn a platform for pure fantasy into a medium for social realism and critique (Raessens 2006). Defining videogames as expressive media carrying messages through their procedural and audio-visual representation systems which can simulate real-life processes,

Ian Bogost points out that the persuasive power of videogames could be used by politicians, political parties, policy-makers, as well as activist citizens, nongovernmental organizations, and by journalists for criticizing, explaining and even for provoking political issues (Bogost et al. 2010). Even though they were overshadowed by the rise of social media, in the last decade these predictions have at least partially came true. Since their first use in 2013 in the USA (Bogost 2007), political election games continue to be produced as part of election campaigns in different countries, like France (Saeed 2017) and the UK (Dallison 2017) during the 2017 elections. Designing video games accompanying political activism or reacting to political turmoil in different parts of the world have become a common practice, as seen in Turkey both during the Gezi Park protests in 2013 (Sezen and Sezen 2016) and after the coup attempt in 2016 (Sezen and Sezen 2018). Finally, since 2011 the Syrian civil war and the following refugee crisis have inspired several games investigating this humanitarian crisis from different perspectives (Stuart 2015; Gach 2017). Even though not as prominent as game scholars have predicted, political video games have become a part of the new media landscape.

Types of Political Games

Focusing on many ways, people use games for political purposes, and both analog and digital games, Lerner proposes three main categories: games about politics, play as political action, and games as political action (Lerner 2014). Games about politics are games about political issues which aim to inform and motivate their players. Their simplest form is what might be called a reactionary political game, a game which addresses a timely political issue without delivering a deep analysis or argumentation and has a very short circulation period. Sicart criticizes such games for being design-wise unoriginal and for not providing any contribution to the political discourse (Sicart 2014).

Play as political action on the other hand inserts game design principles into political practice. One of its famous examples could be considered *the Theatre of the Oppressed* performances by Augusto Boal (1985). Comparing games and play in political context, Sicart argues that play constitutes a much stronger expression of political ideas and continues, "because it is play, it can thrive in situations of oppression; because it is play, it can allow personal and collective expression, giving voices and actions when no one can be heard" (Sicart 2014).

Lerner's last category, games as political action, encompasses games designed to achieve political change. These games are not about politics but are a way of doing politics. "Unlike political play. . ." Lerner says, ". . .these games are structured around specific rules, conflicts, and outcomes" and should be considered tools to make political decisions (Lerner 2014). Analog games used in design processes and activist street games should be considered under this category. The former can be used in areas such as urban politics and the latter can be used as a direct method to achieve political change in the streets and in face-to-face meetings.

Design of Political Games

While the designers' political views may be influential on the level of in-game political agency and critical perspectives of political games, one of the factors affecting these features is time. A game's temporal distance to its topic could be a significant factor over its design choices and consequently over the production specifics, complexity of the game mechanics, stylistic features, and gameplay duration. A short temporal distance between the event and the release of the game usually results with a quick, emotional response as seen in reactionary games. If temporal distance between the event and the release of the game is longer, and during this interval the issue is continued to be discussed and still relevant in the society, it is expected the game as part of the surrounding media ecology might express a political position and contribute to the ongoing discussions. *September 12th*, *Peacemaker,* or *Syrian Journey* might be seen examples of such

process. If though the issue at hand had lost its eminency and relevance, meaning the issue has been closed for the society we may see games akin to political documentaries, analyzing the issue from different perspectives. *1979 Revolution: Black Friday* on 1979 Iranian Revolution or *Ihtilal* (Revolution) on the 1960 coup d'etat in Turkey could be examples.

Going beyond the concept of political themes and events, Mary Flanagan and Helen Nissenbaum propose the term "conscientious designer" to describe those who accept to embody and implement ethical and political values when they design and build systems including games. Political values can be described as arrangements of power and authority, which define relationships within and between societies, such as justice, equality, security, cooperation, tolerance (Flanagan and Nissenbaum 2014). It can be argued that political values are the building blocks or components of individual political themes and issues. A conscientious designer uses game design elements which not only have cultural, ethical, and political resonances, but also are experienced by the players to reflect on political values. According to Flanagan and Nissenbaum, some of these elements can be listed as follows: Narrative premise and goals, characters, actions in games, player choice, rules for interaction with other players and nonplayable characters, rules for interaction with the environment, point of view, rewards, and game maps (Flanagan and Nissenbaum 2014). A conscientious political game designer should be able to analyze individual political issues to identify the values shaping it and later use the game design elements, which would enable her to reflect on them.

Conclusion

There is no single relationship between games and politics, and these relationships continue to grow up in many unexpected new ways. Media outlets, political actors, and institutions explicitly embrace the experimental possibilities of games. Political games are still not a key medium in today's political media landscape, but a unique part of it.

Position Based Dynamics

Tsung-Chih Tsai
Fashion Tech, Nogle, Taipei, Taiwan

Definition

Position based dynamics is a fast, stable, and controllable simulation technique. It directly manipulates the vertex positions of object meshes instead of forces or impulses and can model various dynamic and interactive effects of objects such as rigid body, soft body, cloth, or fluids.

Introduction

Physically based simulation has been an important and active research field in computer graphics. In recent decade, it has become an indispensable component in movies, video games, or interactive applications. In addition, with the rapid growth of the computational capabilities of CPUs and GPUs, there are more and more demands for real-time complicated simulation effects.

The classic simulation method is based on Newton's law of motion to accumulate internal and external forces acting on an object at the beginning of a time step. Then a numerical integration technique like explicit or implicit Euler integrator is further applied to estimate new velocity, and then position at the end of a time step. The former is conditionally stable and accurate if a small time step is adopted. In contrast, the latter is unconditionally stable even though a large time step is adopted, but inaccurate. In order to achieve a trade-off between them, position based method simply adopts a fast semi-integrator, symplectic Euler, to evaluate external force like gravity. Furthermore, instead of gathering internal forces to compute acceleration and velocity, the vertex position is directly manipulated and controlled to solve internal constraints, like stretching, bending, or volume constraint, and collision constraints such as mutual-collisions between objects or self-collisions of an object. Consequently, this method does not only bring the speed and visual plausibility but also the controllability on attached objects or collision handling. Some well-known real-time physics engines such as *PhysX*, *Bullet*, and *Havok* all have integrated the position based method into their systems to simulate soft body or cloth dynamics.

In this entry, we mainly introduce the position based dynamics method (PBD), presented by Müller et al. (2007), and refer to new emerging techniques based on the former.

Overview of Algorithm

PBD presented a particle-based model which combines internal and collision constraints. A deformable object is represented by a set of N particles and a set of M ($M_{\text{inter}} + M_{coll}$) constraints including a fixed number of internal constraints (M_{inter}) and an unfixed number of collision constraints (M_{coll}). At each time step (Δt), the simulation procedure is performed as follows. Before entering the simulation loop, for all N particles, we initiate the current position (x), velocity (v), and mass (m) of each particle to its beginning variables.

1. Gather and accumulate external forces ($f_{ext}(x_i)$) acting on particle i. These forces include

gravity and other forces that are unable to be converted to position based manipulation.
2. Update new velocity (v_i) and predicted position (x_i') by the symplectic Euler method: $v_i = v_i + \Delta t \frac{f_{ext}(x_i)}{m_i}$, and $x_i' = x_i + \Delta t v_i$.
3. Perform discrete or continuous collision detection to collect all overlapping geometries, and generate M_{coll} collision constraints (see section "Collision Constraints").
4. Iteratively solve a set of M constraints one after another in a Gauss-Seidel type fashion, until the solver loop reaches the maximal predefined iteration. While solving a constraint, those predicted positions (x') of particles related to this constraint are all corrected to satisfy the constraint condition (see section "Internal Constraints").
5. After solving constraint loop, the predicted position(xi′) is used to update the velocity (v_i) accordingly, and then set back to the current position (x_i): $v_i = \frac{x_i' - x_i}{\Delta t}$, and $x_i = x_i'$.
6. Lastly, these velocities of colliding particles involved in the collision constraints need to be further modified according to friction and restitution coefficients.

Internal Constraints

An object model does not only consist of a set of particles but also a set of internal constraints such as stretching, bending, or volume constraints. These constraints are to simulate various object materials like soft body or cloth by building an equilibrium system which connects different particles together based on the constraint type. Instead of adopting a classic mass-spring model to evaluate a force based result, the system directly controls the positions and displacements of those particles to satisfy the constraint conditions. In addition, it also must conserve both linear and angular momentums. This means that any rotating or translating the particles does not change the equality of the constraint function $C(x + \Delta x) = 0$. Δx stands for the corrected displacements of all particles, i.e., $[\Delta x_1, \ldots, \Delta x_N]^T$.

The constraint function can be further derived and approximated by the following equation:

$$C(x + \Delta x) \approx C(x) + \nabla_x C(x) \cdot \Delta x = 0$$

where $\nabla_x C(x)$ is a gradient vector and means the maximal change's direction. By restricting Δx to be in the direction of $\nabla_x C(x_1, \ldots, x_N)$, we can derive

$$\Delta x = -\frac{C(x_1, \ldots, x_N)}{|\nabla_x C(x_1, \ldots, x_N)|^2} \nabla_x C(x_1, \ldots, x_N)$$

Then, for the corrected displacement of an individual particle i with an inverse mass $w_i = 1/m_i$, we have

$$\Delta x_i = -\frac{w_i C(x_1, \ldots, x_N)}{\sum_j^N w_j |\nabla_{x_j} C(x_1, \ldots, x_N)|^2} \nabla_{x_i} C(x_1, \ldots, x_N)$$

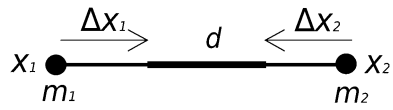
In order to represent the stiffness strength of an object material, the stiffness parameter $k \in [0 \ldots 1]$ is incorporated into the above constraint function. Then, it becomes

$$\Delta x_i = -k' \frac{w_i C(x_1, \ldots, x_N)}{\sum_j^N w_j |\nabla_{x_j} C(x_1, \ldots, x_N)|^2} \nabla_{x_i} C(x_1, \ldots, x_N)$$

where $k' = 1 - (1 - k)^{1/s}$ and s is the iteration count of a constraint solver. Instead of directly multiplying Δx_i by k, k' makes k independent of the solver and more predictable.

Stretching Constraint

For each edge of a triangle mesh, a stretching constraint is built to control the movement of both its vertices, x_1 and x_2. This constraint can be represented as a distance constraint function $C(x_1, x_2) = |x_1 - x_2| - d$, where the scalar value d is the initial distance between x_1 and x_2. Such as Fig. 1, both vertices are projected to the direction of gradient vector $\nabla_x C(x_1, x_2)$, i.e., $\nabla_{x_1} C(x_1, x_2) = n$, and $\nabla_{x_2} C(x_1, x_2) = -n$, with $n = (x_1 - x_2)/|x_1 - x_2|$. Thus, we can get the final displacements as follows:



Position Based Dynamics, Fig. 1 The projection of distance constraint

$$\Delta x_1 = -\frac{w_1 C(x_1, x_2)}{\sum_{j=1}^{2} w_j \left|\nabla_{x_j} C(x_1, x_2)\right|^2} \cdot$$

$$n = -\frac{w_1(|x_1 - x_2| - d)}{w_1 + w_2} \cdot \frac{x_1 - x_2}{|\, x_1 - x_2 \,|}$$

$$\Delta x_2 = +\frac{w_2 C(x_1, x_2)}{\sum_{j=1}^{2} w_j \left|\nabla_{x_j} C(x_1, x_2)\right|^2} \cdot$$

$$n = +\frac{w_2(|x_1 - x_2| - d)}{w_1 + w_2} \cdot \frac{x_1 - x_2}{|\, x_1 - x_2 \,|}$$

Bending Constraint

For each pair of adjacent triangles T1(x_1, x_2, x_3) and T2(x_1, x_4, x_2) such as Fig. 2, we generate a bending constraint with constraint function:

$$C(x_1, x_2, x_3, x_4) = \cos^{-1}(\mathrm{n}_1 \cdot \mathrm{n}_2) - \varphi_0$$

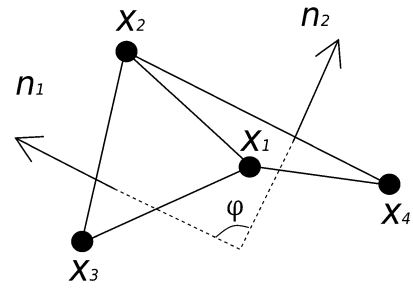
where $n_1 = \frac{(x_2 - x_1) \times (x_3 - x_1)}{|(x_2 - x_1) \times (x_3 - x_1)|}$, $n_2 = \frac{(x_4 - x_1) \times (x_2 - x_1)}{|(x_4 - x_1) \times (x_2 - x_1)|}$, and φ_0 is the initial dihedral angle between T1 and T2. The gradient $\nabla_x C(x_1, \ldots, x_4)$ shows as follows:

$$\nabla_{x_4} C(x_1, \ldots, x_4) = \frac{x_2 \times n_1 + (n_2 \times x_2) d}{|x_2 \times x_4|}$$

$$\nabla_{x_3} C(x_1, \ldots, x_4) = \frac{x_2 \times n_2 + (n_1 \times x_2) d}{|x_2 \times x_3|}$$

$$\nabla_{x_2} C(x_1, \ldots, x_4) = -\frac{x_3 \times n_2 + (n_1 \times x_3) d}{|x_2 \times x_3|} - \frac{x_4 \times n_1 + (n_2 \times x_4) d}{|x_2 \times x_4|}$$

$$\nabla_{x_1} C(x_1, \ldots, x_4) = -\nabla_{x_2} C(x_1, \ldots, x_4) - \nabla_{x_3} C(x_1, \ldots, x_4) - \nabla_{x_4} C(x_1, \ldots, x_4)$$



Position Based Dynamics, Fig. 2 Bending constraint

where $d = \mathrm{n}_1 \cdot \mathrm{n}_2$. Then the final correction Δx_i is as follows:

$$\Delta x_i = -\frac{w_i \sqrt{1 - d^2}\, C(x_1, \ldots, x_4)}{\sum_{j=1}^{4} w_j \left|\nabla_{x_j} C(x_1, \ldots, x_4)\right|^2} \cdot \nabla_{x_i} C(x_1, \ldots, x_4)$$

Volume Constraint

For each closed triangle mesh, a volume constraint is built to maintain its volume and pressure. This constraint function refers to all N particles of the mesh.

$$C(x_1, \ldots, x_N) = \left(\sum_{i=1}^{l} \left(x_{t_1^i} \times x_{t_2^i} \right) \cdot x_{t_3^i} \right) - k_{\text{pressure}} V_0$$

Here l is the amount of all triangles. $x_{t_1^i}$, $x_{t_2^i}$, and $x_{t_3^i}$ represent the three particles of triangle i respectively. $k_{pressure}$ is a pressure factor and used to simulate overpressure status, and V_0 is the original volume of the closed mesh. Furthermore, we can derive the gradient vector $\nabla_{x_i} C(x_1, \ldots, x_N)$:

$$\nabla_{x_i} C(x_1, \ldots, x_N) = \sum_{j : t_1^j = i} \left(x_{t_2^j} \times x_{t_3^j} \right) + \sum_{j : t_2^j = i} \left(x_{t_3^j} \times x_{t_1^j} \right) + \sum_{j : t_3^j = i} \left(x_{t_1^j} \times x_{t_2^j} \right)$$

where $j : t_1^j = i, j : t_2^j = i$, and $j : t_3^j = i$ are the

triangle indices containing x_i in first, second, and third place, respectively.

Collision Constraints

Unlike internal constraints (M_{inter}) which are generated once before simulation, collision constraints (M_{coll}) are detected and generated at each time step before entering the constraint solver loop. In other words, the number of collision constraints varies and depends on actual colliding particles. A collision constraint $C(x_v, x_{t1}, x_{t2}, x_{t3})$ is generated and inserted into the system if the vertex (x_v) hits or penetrates into another triangle (x_{t1} , x_{t2} , x_{t3}). Also, due the collision constraint is an inequality constraint, it will not be performed if the collision does not satisfy the condition of $C(x_1, \ldots, x_N) < 0$. There are both continuous collision and static collision handling methods used to solve different collision cases (Müller et al. 2007).

In order to efficiently detect potential collision and self-collision pairs of deformable objects, a spatial hashing table (Teschner et al. 2003) is built. It can early exclude most of collision pairs which are not colliding with each other. Firstly, the predicted positions of particles and AABBs of triangles are discretized to 3D cell indices with respect to a predefined grid cell size. Then, these cell indices are further mapped into 1D hash index. Lastly, we are able to quickly detect if a particle potentially overlaps with any triangles by checking the same hash index.

As for the collision detection between deformable objects and rigid bodies, bounding volume hierarchy (BVH) (Gottschalk et al. 1996) is built and maintained to speed up the process of culling nonoverlapping parts of the objects. BVH is a tree data structure, and constructed by recursively dividing objects into subsets of geometric primitives. In the meantime, these primitives are enclosed into simple bounding volumes, like spheres, AABB, OBB, or k-DOP and stored into the corresponding tree nodes. By doing the tree traversal recursively and performing simple overlapping tests among bounding volumes, it does not only simplify the collision computations but also reduces the number of collision pairs.

Once a vertex-triangle pair has been detected, continuous collision handling (Müller et al. 2007) is then used to check if the vertex has penetrated into the triangle. We shoot a ray ($x_i \rightarrow x_i'$) for vertex i to perform a ray-triangle intersection test. If this ray hits the triangle, we compute the hit point x_{hit} and the triangle's surface normal n_{hit} at this position and judge whether the inequality constraint function is satisfied:

$$C(x_v, x_{t1}, x_{t2}, x_{t3}) = (x_v - x_{\text{hit}}) \cdot n_{\text{hit}} - h > 0.$$

Here h is a collision margin or surface thickness value. When the above constraint is solved, we can compute the correction $\Delta x_v = h - (x_v - x_{hit}) \cdot n_{hit}$. If the ray hits the front side of the triangle, n_{hit} is computed as follows:

$$n_{hit} = \frac{(x_{t2} - x_{t1}) \times (x_{t3} - x_{t1})}{|(x_{t2} - x_{t1}) \times (x_{t3} - x_{t1})|}$$

In contrast, if the ray hits the back side of the triangle, then we get

$$n_{hit} = \frac{(x_{t3} - x_{t1}) \times (x_{t2} - x_{t1})}{|(x_{t3} - x_{t1}) \times (x_{t2} - x_{t1})|}$$

When a ray is completely inside a closed object, continuous collision handling does not work at this case. At this moment, we apply static collision handling (Müller et al. 2007) to compute the surface point x_s, which is closest to x_v, and the surface normal n_s at this position. Lastly, we can have a modified correction Δx_v:

$$\Delta x_v = h - (x_v - x_s) \cdot$$
$$n_s = h - (x_v - x_s) \cdot \frac{(x_{t3} - x_{t1}) \times (x_{t2} - x_{t1})}{|(x_{t3} - x_{t1}) \times (x_{t2} - x_{t1})|}$$

For the collision handling between deformable objects and rigid bodies, if we need two-way interactions, a correction Δx_v is applied to a deformable vertex. Also, an impulse $m_i \Delta x_v / \Delta t$ is simultaneously applied to the rigid body at the hit point.

The Future

Although position based dynamics is fast, stable, and controllable, it has some limits. The Gauss-Seidel type solver handles constraints one by one individually such that the information propagation is slow and hard to converge. Consequently, it makes deformable object stretchier and results in an obvious visual defect, especially when high-resolution meshes are used. Wang (2015) applied a Chebyshev semi-iterative approach to accelerate the convergence.

Another limit is that the constraint stiffness cannot be completely controlled by the user-defined parameter. It also depends on both the time step size and the number of solver iterations. Specifically, constraints become stiffer and stiffer as the number of solver iterations increases, or as the time step size decreases. Recently, Macklin et al. (2016) introduced a total Lagrange multiplier to PBD and allowed solving constraints to be independent of the above factors.

The position based simulation method is not limited to particle-based models. It also has been used to simulate articulated rigid body systems with joint and contact constraints (Deul et al. 2014).

Macklin and Müller (2013) presented an iterative density constraint solver by formulating and solving a set of positional constraints that enforce constant density. It allows similar incompressibility and convergence to modern smoothed particle hydrodynamic (SPH) solvers (Monaghan 1992).

Macklin et al. (2014) modeled gases, liquids, deformable solids, rigid bodies, and cloth as particle-based models connected by constraints. Also, they treat contact and collisions in a unified manner so as to support two-way interactions with one another.

Position-Aware 3D Facial Expression Mapping Using Ray Casting and Blendshape

Muhammad Anwar Bin Ahmad, Norhaida Mohd Suaib and Ahmad Hakim Ahmad Rahman
Universiti Teknologi Malaysia, Skudai, Malaysia

Synonyms

Blendshape; Position-aware concept; Ray casting

Definition

The usage of blendshapes is one of the methods to partially automate the animating process therefore reducing the workload of the animators. This

entry presents an improved method of animating facial expressions using a technique that combines blendshape, ray casting, and the position-aware concept. Blendshape is a technique to deform geometries to create the desired geometrical morph. Ray casting is a fast visible surface detection method and position-aware concept allows the tracking of an entity's current location and be sent to other entities for further uses.

Introduction

Translating human facial expression into 3D animation that is believable and realistic usually requires animators to manually create the expressions in a 3D software. Many researchers have been studying on how to lighten the workloads on the animators by automating some parts of the process. This entry focuses on the process of minimalizing the complexity and tediousness of adding facial expressions on motion capture (MoCap) data to make it more realistic.

For this entry, the focus is on dance MoCap data. Some MoCap data that is based on dances have no facial animation. Therefore, there is a need to animate the facial expression of data to make it more realistic and believable. However, adding facial expressions manually is a tedious and time consuming process. Thus, this entry discusses the process of semi-automating part on the animating process using a combination of blendshape, ray casting, and position-aware concept.

Blendshape

Blendshape is a technique to deform geometries to create the desired geometrical morph. It is the most common way of deforming facial meshes to create various facial expressions. It is supported by popular 3D modeling software like Autodesk Maya, Autodesk 3DS MAX, and Blender. Usually, modelers often have to create a large library of hundreds of blendshape targets to achieve maximum range of facial expressions to ensure that the character's expressions can be as realistic as possible. For example, the character Gollum from Lord of the Rings blockbuster movie series have a total of 946 blendshape targets (Lewis et al. 2005). On top of that, it is an animator's job to animate those blendshapes which requires more work and time.

Blendshapes have weights which controls the intensity of the expressions. This is usually controlled by sliders or input boxes (Lewis et al. 2014). The flexibility of blendshape is what makes it an intuitive and natural approach to animate facial expression. Using this information, it is possible to map a facial expression by transitioning from an expression to another expression by utilizing the blendshapes in a 3D model. Figure 1 shows an example of blendshape presets. These expressions are stored within the model itself and can be set by changing the weights of the desired expressions.

Aside from manually creating blendshape targets, facial motion capture can also be used to generate blendshape targets. This includes marker-based and markerless motion capture systems. An example of marker-based is the cross-mapping motion capture data by Deng et al. (2006). This system requires a complex and expensive setup but it can generate a high quality dataset. With markerless systems, the setup is less complex and cheaper but the tradeoff is the data generated is lower in quality and usually contain a lot of noises. An example of markerless system is by Saito (2015) whereby she used a combination of Brekel Pro Face, Autodesk Maya 2013, and Autodesk MotionBuilder 2013.

3D Object Detection Using Ray Casting

Ray casting is a technique that has been used for many years to solve computer graphics problems. It was first introduced by Roth (1982) whereby he described the method of rendering constructive solid geometry model. Although it was introduced as a rendering method, ray casting can also be used for other purposes such as object detection and visible surface detection. One of the most notable usages of this technique is in video games such as Wolfenstein 3D and Doom (Vandevenne 2004). Ray casting works by

Position-Aware 3D Facial Expression Mapping Using Ray Casting and Blendshape, Fig. 1 Blendshapes (Lewis et al. 2014)

projecting a line from a model as the view vector. The line will be used for detecting other objects it meets. If the line intersects another object, the system will trigger any event that has been set beforehand. Figure 2 shows an example illustration of how a ray cast works.

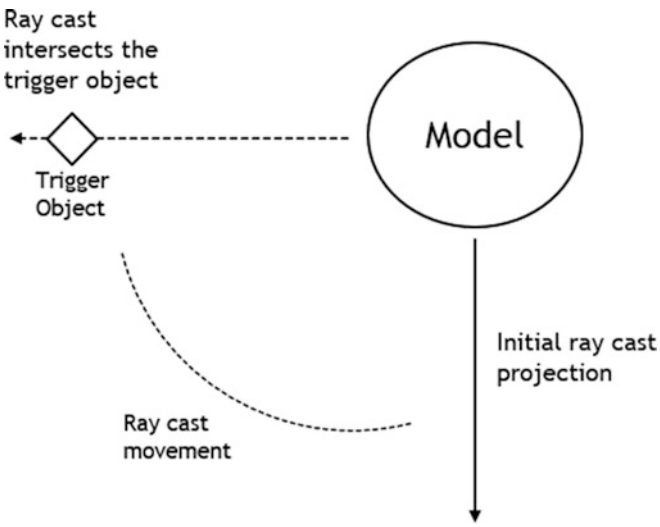
Usually the line represents the view vector of the model. When it intersects the trigger object, the programmer can set the event call for further actions.

Position-Aware Concept

Position or location awareness on a large scale is the technology to track and deliver a device's physical location to other entities such as a user or application. It enables modern devices such as smartphone to share the current geo-location to other users (Bao et al. 2012). This is majorly used in map applications such as Google Maps and Waze. This concept is also used in video games for crowd simulation and Artificial Intelligence (AI) pathfinding. The AI must communicate with other AI and determine their positions to avoid collision. Ondřej et al. (2010) proposed a vision-based steering approach whereby the AI is given a line of sight to determine the other AIs in its surroundings. This ensures that the AI is aware of its current position in the environment and is able to avoid collision with other AI. This can be further improved by implementing human-like gaze to the AI (Narang et al. 2016) which will make the AI have a wider area of viewing since it mimics the vision span of a real human instead of having a straight line vision only. Therefore, this gives more information about its surrounding to make better decision.

Combination of Position-Aware and Ray Casting

Ray casting is a fast technique that is suitable for real time calculations. The idea of combining ray casting with position-aware concept was demonstrated in the 2017 video game titled NieR: Automata developed by PlatinumGames, Inc. In this video game, the sound engineer, Kohata Shuji (2018) developed a sound solution system based ray casting. The goal of this system is to allow the game to simulate reverb and ambience sounds as accurately as possible while maintaining a low cost performance impact. The system projects multiple rays randomly from the player on every single frame. Every time the rays intersect with the objects in the environment, the system would temporarily record the collision points and the sound engine will produce the appropriate sounds. This enables a more immersive and satisfying gameplay.



Position-Aware 3D Facial Expression Mapping Using Ray Casting and Blendshape, Fig. 2 Ray cast example

From this system, the idea of combining ray casting and position-aware concept can be applied to 3D character expression. This technique works by having a ray casted from the face of a 3D model that contains the blendshapes of the expressions and detecting markers designated around the model and maps the correct expression according to the markers. The position-aware aspect of this technique is that the marker's position will determine where the model needs to face for the expression to change. Markers can be placed on specific positions. Then a ray can be casted from the head of the model and at any time the ray intersects with the marker the facial expression will automatically be animated.

Conclusion

In this entry, several techniques and methods that are the component of facial expression mapping using the combination of ray casting, blendshape, and position-aware concept were discussed. This technique manipulates the facial blendshape of a 3D model and considers the position-aware aspect in which the facial expression is changed according to specific location the 3D head model is facing. By using this technique, it is possible to reduce the workload of animators by semi-automating the process.

Post-Digital Graphics in Computer Games

Mattia Thibault
Interdisciplinary Center of Research on Communication, University of Turin, Turin, Italy

Synonyms

Nonphotorealistic rendering; NPR; Post-digital

Definition

Post-digital graphics is a computer game aesthetics that makes use of nonphotorealistic rendering (NPR) inspired by analogue art and craft. The decision of implementing post-digital graphics is often influenced by budget reasons, but is also a choice of design leading to specific aesthetic effects.

Introduction

The post-digital paradigm emerges in a moment when digital technology is endemic and plays a central role in contemporary culture. Every individual in the West continually carries along a powerful computer used to constantly translate their life into digital data (pictures, GPS positions, social relations, etc.). The significance of physical space is questioned by online services allowing citizens to interact with institutions, public administration, banks, and offices without the need to actually travel there. Products such as books, video games, films, and music are increasingly dematerialized and transformed in digital goods.

This digital saturation, after a period of enthusiasm, has started to lead to an inverse tendency: post-digital. According to Cramer (2015) the contemporary disenchantment with digital information systems and technological tools entails a revival of "old" media and artifacts, such as vinyl discs and typewriters. Computer games are also touched by this trend, which gave birth to games such as *Cuphead Don't Deal with the Devil* (MDHR 2017) or *Future Unfolding* (Spaces of Play 2017).

Post-Digital in Indie Gaming

Most of games that exploit a post-digital aesthetics are indie games. There are certainly some exceptions – e.g., *Borderlands* (2 k games 2009) – but the indie scene has more to gain using this graphics.

In the last few years, independent games acquired a stable identity, overcoming the "commercial" definition of "indie" and facing what, according to Juul (2014), has been the biggest game design challenges of indie developers: that of creating their own, specific *style*.

Indie game design faces budget limitations that spur developers to explore alternative solutions and avoid creating low-quality imitations of big-budget games. The small productions of indie games, then, turn naturally to the simpler, yet still efficient, rendering techniques used in games from the 1980s and 1990s. These techniques are obviously easier and cheaper to

implement, even if this pragmatic consideration is only part of the picture. In fact the rise of the indie style described by Juul (Op. cit.) is also due to the appeal that this kind of aesthetics can exercise on players.

The keyword here is "retro gaming," a trend driven by *nostalgia* where games aim, with their aesthetics and gameplay, at creating the illusion of a temporal extension and of bringing back the players to the "good old times."

"Pixilated" aliased graphics accompanied by chiptune music, therefore, became very popular in indie gaming. It is a celebration of *digitalness* that does not hide the digital nature of the game, but exhibits it proudly, answering to the nostalgia for a past state of technology and gaming. Nevertheless, retro gaming should be considered as a first symptom of the digital saturation. It is true that it celebrates the technological and artificial aspect of computer games, but in doing so it also criticizes photorealism, and therefore the (con)fusion between reality and the digital world.

Beyond Realism

Already in 2003 Masuch and Röber, in a somewhat prophetical paper, used several arguments to promote the use of rendering styles alternative to photorealism and foresaw the fall of the totalitarian rule of realism and the rise of a new taste for more dream-like graphics.

According to the authors being "realistic" is not simply a matter of visual resemblance with reality, but also a matter of internal coherence, a feature necessary to give to the virtual world a characteristic of believability. In computer games photorealism is, in fact, less relevant than *immersion,* which depends mainly on the consistency of the graphical representations and on the behavior of in-game physics.

Perhaps surprisingly, NPR techniques are often very believable, as they feel more natural and easy to perceive, and therefore are very good at triggering immersion. Their nonrealistic nature allows a higher amount of deviations without disrupting the image or breaking the atmosphere: ironically, less realism leads to more believability.

NPR games, then, may not "look" as real as photorealistic ones, but are more believable and can be used for artistic purposes: they are able to simulate the style of different media (e.g., comics), and may strengthen the storytelling by shaping the style used throughout the game to evoke emotions, or to establish certain moods.

Post-Digital and Analogue Aesthetics

The intersection of NPR, indie games' typical nostalgia, and post-digital taste is analogue *aesthetics:* a graphic alternative whose influence is becoming more and more important in independent games. Hand-drawn or hand-drawn-like graphics that do not appear (or sometimes are not) digitally generated are increasingly popular.

Developers might opt for a crayon-like rendering (see *Crayon Physics Deluxe* 2009 Petri Purho) or for literally hand-drawn backgrounds and characters (*The Banner Saga* 2014, Stoic); in all cases the digital nature of video games is hidden, denied, while the fictitious nature of the game is brought to the foreground.

Analogue aesthetics, then, on the one hand goes in the opposite direction to photorealism, stressing its unreality and its distance from everyday life, and on the other hand is in open contrast with pixelated graphics of retro gaming because it hides the digital nature of the game under an analogue appearance.

Using analogue aesthetics may have several benefits. It is a way of offering a more nuanced emotional palette and to create original and pleasurable dream-like visuals. It boosts immersion without losing any believability, as long as the graphics are coherent with their own assumptions.

The post-digital flavor of analogue aesthetics should not be considered as a sort of Luddite reaction to digitalness advocating paradoxically calling for a nostalgic return to analogue play. It is more likely the product of a change of paradigm that normalizes digital systems (and does not see "digital" as synonymous of "progress") and therefore is prone to hybridize them with a renewed taste for the analogue.

In other words, after a period where everything that was digital was perceived as more

A screenshot from *Lumino City* (2014, State of Play)

prestigious, the trend is shifting towards a mediation between two ways, exploiting the strengths of both: digital procedural generation and human unpredictability, digital perfection and analogue freedom, digital spreadability and analogue uniqueness.

A very good example of post-digital game is State of Play's game *Lumino City* (2014), a very particular puzzle game telling the story of Lumi, a young girl who follows a series of clues in order to save her grandfather.

This computer game features a perfect balance between digital and analogue. Its developers went beyond the hand-drawn video games mentioned before. The objects and scenario appearing in the game are completely hand-crafted. State of Play members built the entire set of the game out of paper, cardboard wood, some little lights and a custom set of motors. The crafting work and its digitization took 3 years: the team built a 3-m-high miniature city, photographed it, and turned it into a natural-feeling video game world. Although one of the reasons that pushed the developers to adopt this solution was of economical nature, the effect of warmth, the tangible feeling of authenticity, of materiality acquired by the overall experience is probably the main reason of the success of this game. The result of this experiment is a visual aesthetic that is both photoreal and dreamily cartoonesque, a graphic regime able to bridge between digital and analogue and to exploit the strength of both.

Definition

For the purposes of this entry, *postproduction* refers to the creative editorial, color correction, and delivery aspects of video for game cinematic production.

Introduction

In order to help convey narrative or plot elements within a game, designers will often use the tried and tested methods of cinema, the visual language of which is familiar to most gamers.

The challenge is to ensure that the cinematic feels connected to the game world environment and supports the overall story. This does not necessarily mean it must match *aesthetically* with the game itself, but simply that it should feel integrated into the overall design.

By virtue of their linear nature, cinematics necessarily interrupt game play. This is opposed to narration, verbal character exposition, or other storytelling devices which exist as part of the game world. Nevertheless, cinematics can play an important role in scene setting by explaining key concepts of the game (tutorials, character history, scene setting, clues, etc.) in an easily digestible and engaging manner.

Sometimes a "hybrid" of game and cinematic sequence is created where a limited amount of user interaction is still permitted or segues are created to smooth the transition (Fig. 1).

Real Time Versus Non-real Time

The choice of whether to use real-time or pre-rendered "non-real-time" cinematics depends on a number of factors, including design considerations, hardware capabilities, or narrative demands. This decision must be weighed against the benefits and compromises inherent in both strategies. What follows is a summary of the two approaches and an overview of the process employed in both.

Non-Real Time (Pre-rendered)

In this approach, cinematics are played out as prerecorded full-screen movie files using either a proprietary or standard universal file format.

Since the movie is entirely self-contained, the designer can utilize a traditional production methodology. Visual style can be representative of the game world or incorporate live action. (Live action describes traditional filmmaking with a real camera in the real world.)

This approach provides the following advantages:

1. The postproduction process is not dissimilar to any traditional television/movie production and can utilize the same production pipelines. This includes acquisition (live action or CG), editing, color grading, and sound design.
2. It can exploit render technologies that are beyond the capabilities of the game engine or specific gaming hardware.
3. It is possible to utilize assets that are consistent with the game but with much higher detail. Examples might be improved visual effects, physics simulations (cloth, destruction), or elaborate facial animation.

Postproduction in Game Cinematics, Fig. 1 Examples of in-game cinematics from Crysis 3 (l) and Ryse (r). Crysis 3 cinematic is aesthetically similar to the game itself and connects directly to game play, whereas Ryse is more abstract, yet still serving the overall story

4. Overlays (such as Flash (Adobe FLASH, a vector-based graphics application)) can often be used in combination with movie playback to augment the cinematic with dynamically updated material.
5. The movie is consistent across all platforms and devices.
6. The content can be repurposed for trailers or other promotional materials (Fig. 2).

Compression and Codecs

It can be assumed that the output movie will be compressed quite heavily in order to fit within the game disk/download size requirements.

HD (high definition) and 3D movies can be quite large and it is often necessary to restrict the available storage space for them. As a consequence, there is a visual disparity between real-time and pre-rendered content – particularly if attempting direct continuity between them. Modern audiences can spot the switch.

The degree to which the cinematic will be affected depends ultimately on the compression type used. Most "off the shelf" compressors for in-game use are optimized for CG content and employ RLE (run length encoding) type paradigms. These work best with footage that has large areas of uniform color and luminance with low noise.

Visual artifacts can be evident as overall softness in the image, color banding, blockiness (particularly during shot changes), and pixilation. The problem is often exasperated by postproduction techniques such as:

1. Fast editing. Rapid changes in shots can lead to blockiness at edit points, especially if the direction of motion/shot content changes significantly. This can be mitigated somewhat if the compressor allows for key frame placement.

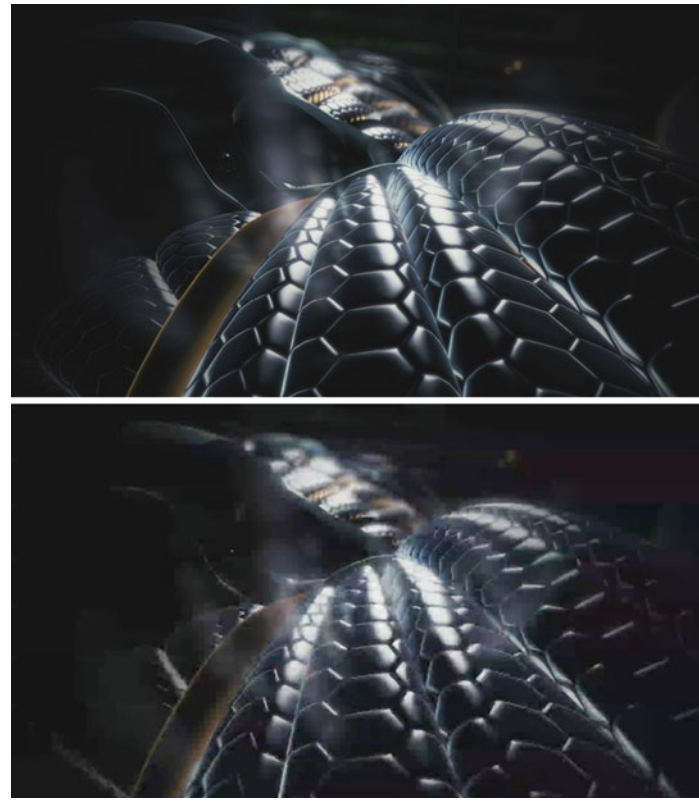
Postproduction in Game Cinematics, Fig. 2 Examples from Ryse of pre-rendered cinematics utilizing game assets

2. Dissolves/fades. These can place a high demand on the compressor since computationally there is often a big difference between the two shots. Transitioning from a night scene to daytime, for example, can be particularly demanding. Fades to/from black can look stepped or blocky in the dark areas of the transition.
3. Cinematic "treatment," such as artificial film scratches, film-burn, or noise. Although these techniques are very popular for lending a "film" style to shots, they also increase the demands placed on the compressor significantly. This is particularly true when working with compressor algorithms optimized for flat-shaded/CG-generated content that struggles with footage which contains live-action "organic" artifacts. Introducing artificial noise, for example, can undermine the regularity in a shot for which the compressor depends on to work effectively.
4. Soft masks/vignettes. These are often employed to create a stylized look to shots and/or used in combination with color grading effects. An issue can arise where the transition areas become blocky and blurry, particularly if the gradient is going to a solid color (Fig. 3).

In all cases, it is necessary to test sequences with the designated compressor and settings to see the results. Striking a balance between performance/space requirements/visual qualities can take time, but it is remarkable how subtle changes to content can make significant improvements to final results: a slight reduction in a lens flare, gamma adjustment, placement of a vignette, and duration of a fade.

Motion Graphics

It is common for motion graphics to be used in order to convey location on a map, character bios, and so on. Designers must be careful not to include very high levels of fine detail, small fonts, or subtle color/brightness graduations which can be lost after compression. Consideration must also be given to the fact that a consumer's display may not be able to resolve the same level of detail or be calibrated as well as that



Postproduction in Game Cinematics, Fig. 3 Extreme example of compression artifacts (amplified for this example). *Top* image is the original, *bottom* image after compression. Note corruption in dark areas (*red rectangle*), lens flare problems, overall loss of detail, gamma shift

of the designers. The "over scan" area of the picture must also be factored in, with sufficient room allocated to compensate for older CRT type displays.

Sometimes it may be more appropriate to use a vector-based renderer to display the motion graphics files directly, rather than include them compressed within movies. Such renderers are often used with HUD (heads-up display) elements (Fig. 4).

Mastering

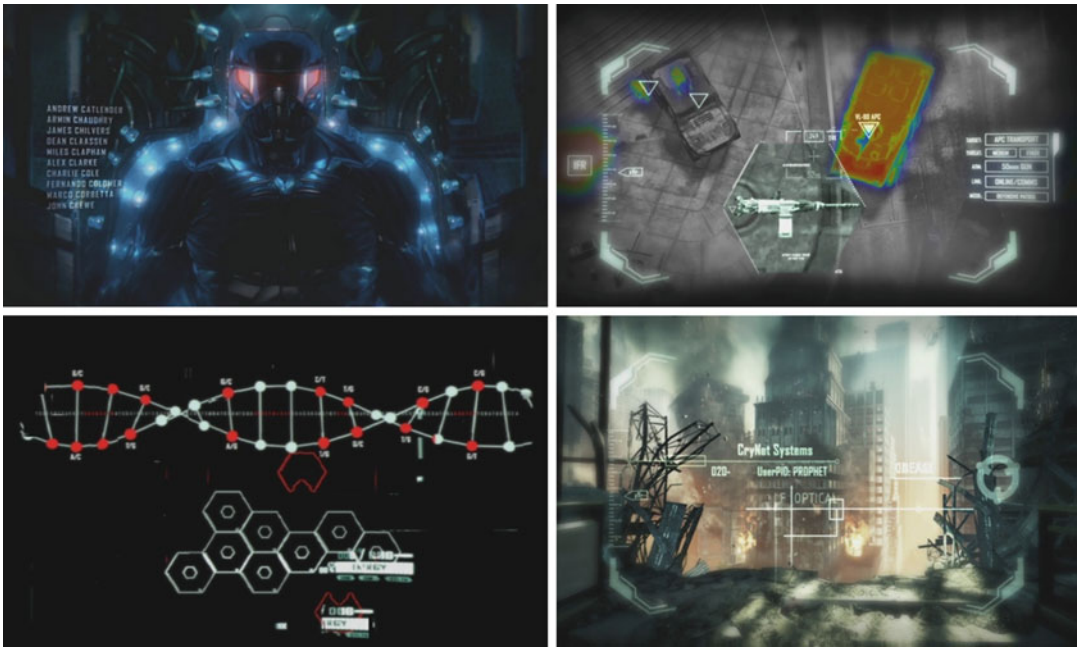
The intermediate and final mastering formats can also impact the final output quality. During all stages of production, it is important to use lossless compression strategies and maintain consistency in color profile/gamma. Any discrepancies can lead to issues with final compression and increase visual disparity between in-game and pre-rendered assets. Gamma and color issues can also occur if the operating space is not interpreted correctly between codecs.

Delivery

The question of delivery format is relevant to any production in today's online world. Playback devices could range from a smartphone LCD display to a theatrical cinema projector. Mitigating the effects of a variety of formats is a constant challenge, and this is particularly the case when working with game cinematics.

Since the movie will be delivered at a fixed frame size and frame rate, it needs to be established early on in production what the requirements will be.

Any changes by the user to the game resolution will also require the movie file to be adapted on the fly. The quality of the scalar will dictate final quality in such cases.



Postproduction in Game Cinematics, Fig. 4 Motion graphics examples from Crysis 2 with vector-based overlays applied to pre-rendered movies

Real-Time Cinematics

As performance capabilities of game devices have improved, designers are increasingly utilizing the in-game engine to render high-quality cinematics in real time.

This provides for several benefits over non-real time:

1. Image quality is consistent with the rest of the game and does not suffer from the compression issues inherent with movie files.
2. Frame size can be adapted on user requirements, rather than being fixed to final video resolution as required.
3. A seamless transition from game to cinematic can be achieved.
4. A degree of user interaction can be included as the cinematic plays out and can therefore feel more "integrated" into the game itself.
5. The cinematic can be adapted depending on the current game state (e.g., a customizable character, object locations, and environmental/time of day factors).
6. The data size footprint of the cinematic can be much lower than an equivalent HD movie, particularly if it utilizes existing game assets (Fig. 5).

However, there are certain factors which should be considered:

1. Each shot change requires not only the camera to be repositioned but also in-world assets, characters, and lighting to be adjusted too. This can lead to a noticeable redraw delay depending on complexity of the scene. This must be considered when designing the sequence.
2. The cinematic is generally restricted to assets that are created for the game environment. This limits the use of third-person perspectives, higher-quality meshes, complex physics simulation, or effects that would otherwise only be possible in pre-rendered sequences.
3. If specific assets are required for use in the cinematic, these need to be loaded and then unloaded from memory. This can result in

Postproduction in Game Cinematics, Fig. 5 Real-time scene setting in Crysis 3 (*top left*) and examples of first-person character exposition

noticeable delays or issues with memory allocation during a sequence.

4. Post effects such as lens flares, noise, film treatment, or masking can be very CPU intensive and restrict their use.

The production process requires careful management to ensure artists can work effectively and in collaboration with each other. For example, level design considerations could conflict with those of the cinematic designers or confine shot perspectives to certain angles. When dealing with dialogue scenes or exposition, the lack of a third-person character model (or a model intended for purposes other than direct viewing) can be problematic. Because of this, and in order to maintain a visual continuity, designers will often opt to shoot the cinematic from a first-person perspective and maintain this until the game resumes. The action therefore plays out more like a stage play, with the user themselves having some degree of control over the "editing."

When it comes to editing the cinematic in a more traditional sense, the tools tend to be those provided by the game engine and are generally not optimized for creating linear content. It is also problematic to interchange data between the engine and more established postproduction environments where seasoned filmmakers are more familiar. Extras loops of effort can be involved in translating between the two worlds.

However, the situation is improving gradually. One current example would be LUT (lookup table) files used in color correction, whereby dedicated grading software can be utilized and the results fed back into the game engine for matching. The importance of intuitive shot editing tools and/or the capability to exchange data with industry standard formats is also being realized.

It is also possible to use storyboarding, off-line edits, mock-ups, or pre-visualization prior to production in order to facilitate the process. Very often these mock-ups will be integrated into the game in some form to test their effectiveness and allow for amendments if necessary.

The aim of all these innovations is to allow the evolved disciplines of filmmaking to play a role in the game cinematic.

Whether real time or non-real time, the purpose of creative storytelling remains the same: to engage and entertain the audience.

Potential of Augmented Reality for Intelligent Transportation Systems

Emerging Networks Laboratory, Telecommunications Software & Systems Group, Waterford Institute of Technology, Waterford, Ireland

Synonyms

Augmented reality; Intelligent transportation systems; Network resource management; Vehicular ad hoc networks; Virtual reality

Definition

Augmented reality (AR) is usually regarded as a human-computer interface which enhances a human's perception of the real world by superimposing useful contextual information in real time (Ling 2017). Over the past few years, AR systems have made remarkable advances in several industries, including aerospace, automotive, robotics, health, military, education, marketing, social media and networking, tourism, gaming, etc. It is anticipated that the next revolutionary wave in industry would come in the shape of a significant dependence on AR devices and systems. In contrast, virtual reality (VR) is a computer-generated three-dimensional immersive experience which is displayed either on a computer display or via special stereoscopic displays, such as Facebook's *Oculus Rift* system.

Introduction and Background

Rapid advances in wireless communication technologies coupled with ongoing massive development in vehicular networking standards and innovations in computing, sensing, and analytics have paved the way for intelligent transportation systems (ITS) to develop rapidly in the near future. ITS provides a complete solution for the efficient and intelligent management of real-time traffic, wherein sensory data is collected from within the vehicles (i.e., via their onboard units) as well as data exchanged between the vehicles, between the vehicles and their supporting roadside infrastructure/network, among the vehicles and vulnerable pedestrians – subsequently paving the way for the realization of the futuristic Internet of Vehicles (IoVs) (Yang et al. 2017). The traditional intent of an ITS system is to detect, monitor, control, and subsequently reduce traffic congestion based on a real-time analysis of the data pertinent to certain patterns of the road traffic, including traffic density at a geographical area of interest, precise velocity of vehicles, current and predicted travelling trajectories and times, etc.

However, merely relying on an ITS framework is not an optimal solution. In case of dense traffic environments, where communication broadcasts from hundreds of thousands of vehicles could potentially choke the entire network (and so could lead to fatal accidents in the case of autonomous vehicles that depend on reliable communications for their operational safety), a fall back to the traditional decentralized vehicular ad hoc network (VANET) approach becomes necessary. It is therefore of critical importance to enhance the situational awareness of vehicular drivers so as to

enable them to make quick but well-founded manual decisions in such safety-critical situations. Modern-day vehicles that utilize sophisticated cameras and radars to project front/rear images and to detect obstacles, respectively, need to present this contextual information to drivers in ways that inform and do not distract them. Conventional displays mounted on dashboards or middle consoles divert the attention of drivers from the primary task of driving. Also, contextual information in these displays is not usually superimposed, and if superimposed, it is presented in a higher degree of detail which not only increases the cognitive load of the drivers but also adds to the overall delay of responding to an unforeseen event. This is where AR comes into play, which, unlike its predecessor (i.e., virtual reality), *enhances* a driver's perception by superimposing useful real-world context in minimal detail in a driver's line of sight.

AR is realized by executing the following four basic tasks (Glockner et al. 2014):

Scene Capture. In the first stage, reality is captured either by employing a video-capturing device (camera) or a see-through device (head-mounted display).

Scene Identification. Once the reality has been captured, it should be scanned in order to identify a particular position where the respective virtual content should be embedded. This position may be identified with virtual tags (markers) or tracking technologies such as sensors, laser, infrared, or GPS.

Scene Processing. Once the captured scene is completely identified, its corresponding virtual information needs to be requested from a database via the Internet. The associated information, with up to the minute detail, is accumulated and subsequently processed in the cloud (either at the network edge or remote cloud) with sufficient compute resources to filter the minimal useful virtual content.

Scene Visualization. Lastly, the AR system generates an amalgamated image of the real scene with the superimposed virtual content, which is subsequently displayed in the driver's visual field.

AR is regarded as one of the several key technology enablers which could set up the conditions for a "perfect technological storm" in the coming decades, as illustrated in Fig. 1. It is interesting to note that the video-processing aspects of AR, in convergence with some of these other technology enablers, could meet many of the more difficult requirements of future autonomous vehicles. The widespread adoption of such vehicles would eventually lead to the realization of next-generation ITS frameworks and smart cities. Apart from the automotive sector, AR is anticipated to revolutionize many industries, including manufacturing, healthcare, education, logistics, architecture, military, gamification, and data centers (Uchida et al. 2017).

AR requires specialized hardware and software, and the development and implementation of this software relies on a highly capable, state-of-the-art hardware and networking. These have been the subject of ongoing research and development by scientists and engineers in the domains of microprocessors, sensors, display systems, battery life, high-resolution cameras, mobile internet speeds, and more. At the time of writing (2018), the "industry best practices" in terms of available AR hardware include handheld devices (*smart phones and tablets*), stationary AR systems (*AR wardrobes*), spatial AR systems, head-mounted displays (*Oculus Rift*), smart glasses, smart contact lenses, etc.

The Need and Potential of Augmented Reality for ITS

Since the advent of automobiles as early as the mid-nineteenth century, each vehicle has been driven by a single human driver, according to his/her requirements, preferences, etc. However, with massive increases in vehicular traffic leading to road congestion and soaring energy costs, the potential benefits of cooperative driving, especially "*platooning*" has received attention.

M2M Communication (Embedded Sensors in Machines and Products)

Mature & Secure Cloud (Balancing Central & Local Data)
3D Printing (Make-To-Individual Manufacturing a Reality)

Potential of Augmented Reality for Intelligent Transportation Systems, Fig. 1 Powering technological innovation – key technology enablers for Industry 4.0

Vehicle platooning aims to significantly reduce the inter-vehicular distances relative to that recommended for manual driving. This is achieved by (1) making driving more predictable by sharing common objectives rather than having individual drivers make uncoordinated decisions and (2) by partially or fully automating common driving tasks, offering faster reaction times than could be achieved by unassisted human drivers. Hence, the smaller the space between vehicles becomes, the more vehicles can be packed in that (finite) road space, thereby increasing road capacity. A supplementary benefit of closer vehicle placement is that it can lead to reduced aerodynamic drag, thereby increasing energy efficiency (Qiu et al. 2017).

Nevertheless, significantly reducing inter-vehicular distances also needs to be safe. This aspect (safety) has been studied in the ITS research literature and highlighted as one of the main challenges hindering the full realization of ITS. Accordingly, significant technological advances in autonomous vehicles and advanced driver assistance systems (ADAS) have been made over the years that have completely altered our perception of transportation safety. Google, Delphi, Tesla, Mercedes-Benz, Porsche, Nissan, and Bosch (to just name a few) are already testing safely driven autonomous vehicles and numerous intelligent ADAS functions, such as lane departure warning, collision warning, autonomous emergency braking, and adaptive cruise control. Some of these are now being offered as options in production vehicles (Kaur and Sobti 2017). Nevertheless, in spite of these technological developments, road accidents continue to happen due to human factors such as misjudgments and erratic human behavior. Research studies (Rameau et al. 2016; Abdi and Meddeb 2018) have analyzed the causes of fatal traffic accidents. Head-on collision as a result of overtaking at high speed is one of the major causes of road fatalities

Potential of Augmented Reality for Intelligent Transportation Systems, Fig. 2 Depicting human behavior in overtaking scenarios – conventional driving scenario

and generally occurs due to occlusion (blocking) of the overtaking driver's field of view, as depicted in Fig. 2. AR could be extremely beneficial here by enabling the overtaking driver to "see through" the slow-moving lorry to the vehicles immediately preceding it and thus make safer overtaking decisions.

Such enhanced situational awareness is highly valuable, given all the in-vehicle secondary tasks assigned to the driver, from adjusting the temperature and ventilation to conversing with other passengers. In the autonomous cars of the future, distractions will be even greater: infotainment for listening to music, making and/or receiving calls, reading and/or sending emails, etc. Also, the level of attention required while driving varies according to the conditions, as driving in dense fog or heavy rain and snow usually requires a higher degree of risk awareness compared to driving on a sunny day with a clear view. Thus, limited visibility and driver distractions pose grave threats to situational awareness and can cause serious road accidents. Also, providing a driver with excessive data results in higher cognitive workloads and weaker driving performance (Contreras et al. 2017). Furthermore, while current sophisticated driving systems can support drivers by providing detailed information, the presentation systems generally require drivers to divert their attention to displays mounted on dashboards or middle consoles. This is where AR comes into play by rendering *critically important* information in a driver's line of sight, thereby decreasing both cognitive workload and distraction while driving. However, it is pertinent to note that the information being displayed should be carefully chosen. It should be derived from a wide variety of onboard sensors, enhanced with data from the roadside and other vehicles, shared over wireless links, and intelligently extracted with sufficient but not excessive detail. Remote data can be shared using vehicle-to-vehicle (V2V), vehicle-to-infrastructure/network (V2I/N), and vehicle-to-pedestrian (V2P) communication.

Potential of Augmented Reality for Intelligent Transportation Systems, Table 1 Example link layer parameters for V2X services

Scenarios	Effective range (meters)	Absolute speed of UE (km/h)	Relative speed b/w two UEs (km/h)	Tolerable latency (ms)
Major roads/suburban	200	50	100	100
Motorway/freeway	320	160	280	100
Autobahn	320	280	280	100
Non-line of sight/ urban	150	50	100	100
Urban intersections	50	50	100	100
Shopping area/campus	50	30	30	100
Imminent crashes	20	80	160	20

Source: 3GPP Technical Report 22.885 v14.0.0 (3GPP 2015)
It should be noted that there are various parameters involved in these scenarios, i.e., physical (relative speed, effective range), incidental (line-of-sight occlusion), and service-related (maximum tolerable latency). These parameters can be derived from the principle that there should be more than 95% probability that a vehicle has received at least one V2X message from two consecutive V2X messages notifying it of any impending incident.

Also, it is essential to display this information with very low latency: the maximum tolerable delay in the case of safety-critical vehicular applications is in the range of 20–100 ms as depicted in Table 1.

The Need for Intelligent Network Resource Management in ITS

The low-latency requirements of safety-critical vehicular applications increase the demand for intelligent and efficient network resource management, because vehicular AR applications have numerous parts that need to be managed. At present, the number of sensors on vehicles is approximately 100, and this number is expected to double by 2020. According to Intel estimates, autonomous vehicles are anticipated to generate and consume 5 TB of data for every hour of driving, and the primary reason for this appetite is the growth of onboard sensors with automotive cameras and radars alone generating 20–40 Mbps and 100 kbps of data, respectively (Nelson 2018). ITS networks also need to support additional data streams such as that generated by humans (vehicular users and roadside pedestrians). As estimated, vehicular users on average consume around 650 Mbps of videos, chat, and Internet usage per day, and this is anticipated to increase to 1.5 Gbps per day by 2020. The third source of data arises from certain crowd-sourced traffic platforms, such as Google Waze. Processing such big data arising from hundreds of thousands of vehicles requires extremely high computational power and intelligent machine learning algorithms to extract critically important information to be rendered for each driver.

Furthermore, unlike traditional networks, VANETs are highly distributed in nature, and owing to the high mobility of vehicles, the geospatial environmental context also changes rapidly, leading to a dynamically changing network topology. Traditional networking architectures were designed for more static contexts and are thus unable to cater for such challenges. Consequently, there has been a shift toward a more agile approach to ensure reprogrammability, scalability, flexibility, and elasticity. The emerging and promising paradigm of software-defined networking (SDN) together with edge-based computing can help to meet these challenges. SDN decouples the data plane from the control plane, and network intelligence is passed on to a logically centralized controller that is responsible for automating and orchestrating the network operations. Edge-based computing brings network resources, i.e., both compute and storage, nearer to the edge and proves extremely useful when caching frequently requested safety-

critical and non-safety (i.e., infotainment) applications and services, thereby reducing network delay by mitigating excessive network management overhead.

Conclusion

In most countries, the use of private motor vehicles has been on the rise, as consumers are drawn to the flexibility and convenience of such vehicles. Given associated trends such as increasing urbanization with the potential for increasing road congestion, the need for safer urban road environments has become more acute. Thus, the management of urban traffic demands a balance between throughput, safety, efficiency, and sustainability. Private motor vehicles need to share the roads with other modes of transport (i.e., public transport, bicycles, and pedestrians); this also adds to the complexity. Every road accident is one too many, especially when it results in severe injuries or the loss of human life. According to one estimate (Oh et al. 2016), more than 80% of road accidents worldwide happen due to the negligence of drivers or other human errors. Though there have been many sophisticated road safety technologies introduced over the past few years to enhance road safety, many of them resulted in distraction or cognitive overload for the drivers concerned. There is only a limited amount of visual stimuli to which drivers can attend, understand, and react without taking their eyes off the road, and it is essential to present drivers with only critical contextual information in minimal detail within their line of sight so that the right decisions can be made at the right time. This manuscript outlines the significance and need of AR in general and especially for the ITS domain and indicated some of the networking requirements necessary for its successful realization. Nevertheless, there are still many practical challenges, i.e., interpreting digital data, deriving meaningful graphics, and subsequently scaling it, without information loss, to suit the perspective of an individual's visual field, ensuring precise low-latency tracking and monitoring, developing seamless optical displays, etc. All of these need to be addressed so that AR for next-generation ITS platforms can achieve its full potential.

Definitions

Immersion is user's engagement with a VR (virtual reality) system that results with being in a flow state. Immersion to VR systems mainly depends on sensory immersion, which is defined as "the degree which the range of sensory channel is engaged by the virtual simulation" (Kim and Biocca 2018).

Presence within the context of virtual reality is defined as one's sense of being in the virtual world. The illusion is perceptual but not cognitive, as the perceptual system identifies the events and objects and the brain-body system automatically reacts to the changes in the environment, while cognitive system slowly responds with a conclusion of what the person experiences is an illusion (Slater 2018).

Even the VR professionals may mistakenly use the terms "presence" and "immersion" interchangeably; immersion stands for the objective level of sensory fidelity provided by a VR system (Slater 2003), whereas presence is the subjective psychological response of a user experiencing a VR system.

Conceptualizations, Discussions, and Evaluation

Immersion

Immersion is a controversial term due to multidisciplinary adoption of the term by researchers in the fields of virtual reality, narrative, and digital games. Even in the VR literature, there are conflicting definitions of immersion. Early studies (see Nash et al. 2000) focus on the immersion as a technical concept which point to "the extent to which the computer displays are capable of delivering an inclusive, extensive, surrounding and vivid illusion of reality to the senses of a human participant" (Slater and Wilbur 1997). On the contrary, it is also defined as a "psychological state characterized by perceiving oneself to be enveloped by, included in, and interacting with an environment that provides a continuous stream of stimuli and experiences" (Witmer and Singer 1998). Boundary of the term was expanded

to cover interactions with non-VR computer systems such as desktop systems and even non-technologically mediated interactions such as storytelling (Brooks 2003). Despite the focus of his work was narrative immersion, Brooks (2003) also emphasizes on sensory immersion, suggesting that "sights and sounds by immersive media can cause a strong visceral and cognitive belief in what is experienced" and "virtual reality environments (VRE), or immersive environments, are so called because the participant is sensually immersed or surrounded by computer-controlled media." Even he broadens the term to cover the mental and emotional engagement of the participant, he still refers to the physical aspect of immersion. Baños et al. (2004) make a distinction between the media form (e.g., the extent of sensory information presented, the degrees of control that users have over positioning their sensors within the environment, users' ability to modify aspects of the environment) and media content such as objects, actors, and events represented by the medium. It is possible to name these two aspects of medium as sensory and narrative. Brown and Cairns (2004) mention game atmosphere that is composed of graphics, sound, and plot as a determinant of total immersion. They suggest that when gamers attend to sound as well as sight, they invest more attention and effort into the game, leading them to feel more immersed into the game. Clearly, these are also the sensory determinants of immersion. Ermi and Mäyrä (2005) propose a model for gameplay experience, based on sensory, imaginary, and challenge-based immersion. Sensory immersion is observed relying on audiovisual components of the game.

Recent studies in VR (e.g., Diemer et al. 2015) embrace the definition of Slater and Wilbur (1997), regarding immersion as "as a quality of the system's technology, an objective measure of the extent to which the system presents a vivid virtual environment while shutting out physical reality." Considering the subjective nature of presence, Diemer et al. (2015) propose "an interoceptive attribution model of presence," where immersion including interactivity is defined as system factor and perception and information provided by the VE is defined as the content. Because of "immersion and the degree of arousal they feel," "users make a judgment of the degree of presence they feel in VR."

A Framework for Defining Presence

As an essential component of VR experience, there is an agreement on three common features of presence: (1) presence requires involvement into the virtual environment; hence, the effectiveness of VEs is linked to the sense of presence reported by users; (2) presence is defined as a subjective experience; and (3) presence is a multidimensional construct (Gaggioli et al. 2003a).

In the early 1990s, at the time that VR technologies were evolving into consumer-level products, researchers also concentrated on "defining the virtual reality in terms of human experience rather than technological hardware" (Steuer 1992), and the concept of (virtual) presence became a subject of scholarly interest as a dependent measure of individual experience in VR. According to Biocca and Delaney (1995), VR systems may had already crossed a "psychological threshold, a point at which our perceptual systems are so immersed in the simulation that the user already begins to feel some of the sense of 'being there,' the early flushes of a powerful presence." This human experience-oriented approach to VR ignited a still ongoing debate about the definition of "presence" (Barfield 2016).

The concept of presence became a VR-related topic since Sheridan (1992) suggested that it could be applied to a virtual environment as a special case of teleoperation in which the remote site is virtual rather than real. Using the term as "virtual presence," he described the concept as "sense of being physically present with visual, auditory, or force displays generated by a computer."

One of the most referred definitions of presence is simply articulated as "sense of being there," sense of being in one place or environment (i.e., a virtual environment) even when one is physically situated in another (Minsky 1980; Heeter 1992; Witmer and Singer 1998). Although the term is simply articulated as "presence," the VR-related research is mainly focused on "spatial presence," a technology-mediated experience

which is different from "natural" or "proximal" presence that human beings are subjected to in their real-world experience.

On the other hand, the phenomenon of presence is not specific to VE's and teleoperation systems. Scholars in communication studies and psychology explored the concept, and they provided divergent and overlapping definitions. Lombard and Jones (2015) suggested a framework to organize the efforts to define the concept of presence in different disciplines. According to their framework, presence in VR can be defined as a technology-mediated phenomenon and focuses on subjective experience of the person that is triggered by external stimuli that leads to an inaccurate perception of technology involvement. The primary interests of definitions within this scope could be spatial presence, social presence, engagement, and realism.

Presence as a Technology-Mediated Phenomenon

The first layer of Lombard and Jones' framework (2015) organizes the presence definitions by questioning the involvement of technology, denoting that some definitions explicitly exclude the technology while others state that presence may occur with or without technology, as the third subset of definitions explicitly involve technology. A detailed description of technology was given as "a machine, device, or another application of human industrial arts" that are not only limited to traditional and emerging electronic media, traditional print media, and traditional arts but also include "technologies used to correct deficiencies in 'normal' perception of the physical world (e.g., eyeglasses and hearing-aids) as well as those designed to augment or enhance perception" (International Society for Presence Research 2000). Furthermore, since the current technologies depend on providing stimuli for sensory organs, future technologies that may directly stimulate the human neural processing system were considered within the definition of technology related with presence. Lombard and Jones (2015) preferred the term "telepresence" for historical reasons, to point out technology-mediated presence. The primary condition to define presence within the context of VR is to emphasize mediation of technology. Steuer (1992) denoted that "telepresence is defined as the experience of presence in an environment by means of a communication medium." Witmer and Singer (1998) emphasized mediated nature of telepresence as "the subjective experience of being in one place or environment, even when one is physically situated in another." Biocca et al. (2003) refer to "spatial cues and the mental models of mediated spaces" which create "the illusion of place." Waterworth and Waterworth (2003) define "electronically mediated presence" as a perceptual illusion. All these definitions emphasize the mediated nature of presence in VR.

Presence as a Subjective Property of Person

On the second layer, Lombard and Jones' (2015) framework "concerns whether the phenomenon being defined is an objective property of a mode of communication, technology, person, object or entity, or a subjective property of a person." Having an objective perspective on mode of communication, Zhao (2003) defines mediated presence as "a form of human co-location" where people "are located in each other's electronic proximity rather than physical proximity." Floridi (2005) also has an objective perspective while he defines presence as a property of entity depending on entity being located in a local or remote space of observation and being observed in level of abstraction. Although these definitions emphasize the objective nature of mediated presence, several authors denoted the subjective nature of presence as an "experience" or "perception" of an individual calling presence "a psychological phenomenon" (Sas and O'Hare 2003), an "experience" (Steuer 1992), a "subjective feeling or mental state" (Sheridan 1992), and "a psychological state" (Lee 2004). Suggesting a focus on users' subjective experience rather than how the technology mimics the virtual world, Heeter (1992) offered to investigate presence as subjective personal presence, social presence, and environmental presence. These definitions focus on the subjective nature of presence in VR.

Several studies focus on effects of the individual characteristics and the personality traits on presence (see Galloso et al. 2016; Ling et al. 2013), providing further evidence that interpersonal differences affect the "ability to experience the VRE as real and vivid" (Wallach et al. 2009).

Presence as an Experience Triggered by External Stimuli

The third layer of Lombard and Jones' (2015) framework focuses on "source of the stimuli," which can only be explored in terms of presence as "subjective property of a person." Some definitions of presence take the source of stimuli only as external as "impingements on the senses from the physical world outside the body" (Lombard and Jones 2015), as "experience of one's physical environment" (Steuer 1992), as "the feeling of being located in a perceptible external world around the self" (Lombard and Jones 2015), "as the feeling a conscious organism experiences when immersed in a concrete external world" (Waterworth and Waterworth 2003), or as an experience that is "defined as a person's observation of and/or interaction with objects, entities, and/or events in her/his environment" (International Society for Presence Research 2000). Some authors suggest that the stimuli triggering the experience could either be external or internal, as in Biocca's (2003) model, in which presence may occur between the three poles: physical space, virtual space, and internal imagery space.

Presence as an Inaccurate Perception of Technology Involved

The fourth layer of Lombard and Jones' (2015) framework explore the accuracy in perception of technology. For presence in VR, users have an inaccurate perception of technology. They perceive that technology is not involved in the experience, although it is. There is a "perceptual illusion of non-mediation," suggesting that a user experiences presence when he fails to perceive or acknowledge that the environment is being presented to him through some type of media such as television or HMDs (Lombard and Ditton 1997). In virtual presence "the stimuli of a proximal environment created by a presence medium in simulation of the intended environment, which is either inaccessible or nonexistent, press upon the sense organs of the perceiver" and "sense of presence is the subjective experience of being present in an intended environment outside one's body" (Zhao 2002).

Primary Interests of Defining Presence in VR: Spatial Presence, Social Presence, Engagement, and Realism

At this point, Lombard and Jones's framework suggest several aspects of primary interest for the presence phenomenon as the fifth layer of their definition categories. When the primary interest is the physical environment, the definition is related to spatial presence, that can be described as "the subjective experience of being in one place or environment, even when one is physically situated in another" (Witmer and Singer 1998) or "phenomenal sense of 'being there' including automatic responses to spatial cues and the mental models of mediated spaces that create the illusion of place" (Biocca et al. 2003). Some definitions of presence have a primary interest in engagement, as in Jacobson (2002) stating that "presence is the experience of being engaged by the representations of a virtual world" which "often involves a strong connection with the content and/or form of an experience" (Lombard and Jones 2015) and related to distinct but closely related concepts such as attention, involvement, flow, absorption, and (perceived) immersion (Schubert et al. 2001; Witmer and Singer 1998). Realism is another aspect of presence that is of interest, focusing on the correspondence between a technology-mediated experience and a similar experience not mediated by technology. Slater (2003) defined presence with an emphasis on realism, as "response to a given level of immersion (and it only really makes sense when there are two competing systems – one typically the real world, and the other the technology delivering a given immersive system)," while Lee (2004) stated that presence is "a psychological state in which virtual

(para-authentic or artificial) objects are experienced as actual objects in either sensory or non-sensory ways." Zahorik and Jenison (1998) emphasize on the successfully supported actions within the environment and suggest that when "the environmental response is perceived as lawful, that is, commensurate with the response that would be made by the real-world environment in which our perceptual systems have evolved, then the action is said to successfully support our expectations." These definitions focus on the perceptual realism. On the other hand, Lombard and Ditton (1997) define the phenomenon as "the extent to which a media portrayal is [perceived as being] plausible or 'true to life' in that it reflects events that do or could occur in the non-mediated world" and suggest that the plausibility is not limited to perceptual realism but also refers to the narrative being "true to life," which is social realism. Social presence is related to social entities, and definitions generally involve people and/or electronic representations of people, such as "the feeling of being socially present with another person at a remote location" (Sallnäs et al. 2000) or "mutual interaction with a perceived entity refers to the degree of initial awareness, allocated attention, the capacity for both content and affective comprehension, and the capacity for both affective and behavioral interdependence with said entity" (Harms and Biocca 2004). Their study also focuses on interpersonal interactions whereas the given description refers to an entity that can be non-human, such as an NPC (non-person character) or an agent with artificial intelligence.

Measuring Presence

Laarni et al. (2015) classified the methods of measuring presence as objective and subjective methods and criticized these methods. Subjective methods are post-test rating scales in form of questionnaires, continuous subjective presence assessment techniques which employ a slider or counter, psychophysical methods such as magnitude estimation and paired comparisons which produce interval scaled data, and qualitative methods such as interviews, focus groups, think-aloud sessions, ethnographic techniques, experience sampling method, and repertory grid analysis. Objective measures are behavioral, performance-based, and physiological measures of presence.

Subjective Measures

Post-test rating scales hold an important place in the evaluation of presence due to the subjective nature of phenomenon (Insko 2003). Within the early efforts, several remarkable attempts are Slater-Usoh-Steed (SUS) (Slater et al. 1995) questionnaire and Kim and Biocca's (1997) questionnaire. Hendrix and Barfield's (1996) efforts lead to a questionnaire that assesses presence and realism.

Further studies investigate the concept of presence as a multidimensional construct, as Witmer and Singer's (1998) Presence Questionnaire (PQ), which mainly investigates several attributes of VEs that could influence the sense of presence. PQ pairs up with ITQ (Immersive Tendencies Questionnaire) which measure differences in the tendencies of individuals to experience presence. ITQ evaluates users' tendency to become involved in activities, maintain focus on current activities, and play video games as three dimensions, while PQ evaluates the degree that VE provided using items related with involvement/control, naturalness, and fidelity of sensory modalities in terms of resolution, interface quality, auditory, and haptic feedback. Although it is expected that PQ and ITQ scores would always be positively correlated as revealed in Witmer and Singer's original work since a person's tendency to be immersed in a VE would lead to sense of presence, evidence from later studies are mixed. Thornson et al. (2009) developed the "Tendency Toward Presence Inventory" with an approach like ITQ, but their focus is "solely on the individual difference predictors of the tendency to experience presence and not on the environmental factors."

Sas and O'Hare (2003) suggested to measure presence through two primary consciousness dimensions of "being in the VE" and "not being in the VE" with a third dimension of reflective

consciousness that represents awareness of self and outside world. Biocca et al. (2001) attempted to measure presence with 18 items in 3 dimensions: spatial presence, tactile engagement, and sensory presence.

I-Group Presence Questionnaire (IPQ) (Schubert et al. 2001) was developed employing several items from previous research among original items suggested by authors. The 16-item scale evaluated presence in terms of spatial presence, involvement, and judgment of realness.

Independent Television Commission-Sense of Presence Inventory (ITC-SOPI) (Lessiter et al. 2001) measures presence with 44 items using 4 subscales: sense of physical space, engagement, ecological validity, and negative effects. The respondents in the original study were exposed to 2D and 3D IMAX movies, a projected movie recorded on VHS, a short video on a 28-inch TV, and a console computer game. ITC-SOPI was applied in VR studies later (e.g., Baños et al. 2004; Baus and Bouchard 2017).

MEC-SPQ (Project Presence: Measurement, Effects, Conditions-Spatial Presence Questionnaire) (Wirth et al. 2007) has 9 dimensions conceptualized within two levels: Spatial Situation Model as the first level and Spatial Presence as the second level. Besides media factors affecting both levels, Spatial Situation Model dimension is constructed through the process factor named Attention/Allocation. A trait-like dimension called Spatial Visual Imagery also contributes to the construction of the Spatial Situation Model dimension while the Attention/Allocation dimension is influenced by another user trait: Domain-specific Interest dimension.

On the second level, Spatial Presence is constructed depending on the Spatial Situation Model. At this level, dimensons regarding to state and actions of user, Higher Level of Involvement and Suspension of Disbelief influences the construction of Spatial Presence. Another user trait dimension, Absorption induces Higher Level of Involvement and Suspension of Disbelief dimensions. Spatial Presence is measured within two dimensions: Self-Location and Possible Actions (Laarni et al. 2015). Each of these subscales can be applied as four-item, six-item, or eight-item versions. Spatial Experience Scale (SPES) (Hartmann et al. 2015) is a short-form spatial presence scale based on the "self-location" and "possible actions" subscales conceptualized in MEC-SPQ. Pictorial Presence Self-Assessment Manikin (Weibel et al. 2015) uses six of the dimensions conceptualized in MEC-SPQ to measure presence using visual material instead of verbal items.

The Tempe Presence Inventory (TPI) (Lombard et al. 2009) has 42 items within the subscales related with social presence which are parasocial interaction, passive interpersonal presence, active interpersonal presence, social richness, and social realism besides 3 subscales of spatial presence, engagement (mental immersion), and perceptual realism.

Suggesting that there are temporal variations during the exposure to a VE, several studies used a handheld slider controlled by participants to indicate their level of presence continuously during the immersion (see Wissmath et al. 2011). Slater and Steed (2000) used a click-counter that participants use when they feel that they have switched from virtual environment to real world, counted as "breaks in presence." Although these methods aim to be unobtrusive, they require users' attention to provide a continuous measurement during the experiment.

Magnitude estimation and paired comparison were offered for measurement of presence (Stanney and Salvendy 1998), but these methods were not directly to measure presence in virtual reality yet, except magnitude estimation used for evaluating "conflict perceived" between haptic and visual feedback of a system (Kuschel et al. 2007).

Some other subjective qualitative methods that had been used in presence research were interviews, think-aloud sessions (Turner et al. 2003), experience sampling (Gaggioli et al. 2003b), repertory grid analysis (Steed and McDonnell 2003), focus groups (Heeter 1992; Freeman and Avons 2000), and ethnographic observations (McGreevy 1994).

Objective Measures

Objective measures of presence "are difficult to implement for virtual presence" (Nash et al. 2000) due to subjective nature of the phenomenon.

Adopting a behavioral perspective along with a subjective approach, Slater et al. (2009) suggested that "presence refers to how realistically participants respond to the environment as well as their subjective sense of being in the place depicted by the VE." One of the behavioral measures used in presence research is direct observation of adaptive behaviors evoked by virtual dangers (Insko 2003; Lepecq et al. 2009; Slater et al. 1995). Some of these studies provided evidence that users' adaptational behaviors are correlated with the subjective measurements of presence, but it should be noted that only highly immersive VEs evoked these adaptational behaviors. There is also counter-evidence that fidelity of the VE does not affect the performance of users (Vignais et al. 2010) so that presence and performance are not likely to be correlated. Body movements and postural sway were also investigated as indicators of presence (e.g., Slater and Steed 2000; Stanney et al. 2002). Guerraz and Bronstein (2008) verified the relationship between visually induced illusion of self-motion and automatic postural adjustments but revealed that postural sways occur prior to conscious sense of vection. Attention-based measures of presence explore the users' awareness of stimuli in the real-world ambience, while they were immersed in a virtual environment (e.g., Slater et al. 1995).

Performance measures of presence are based on the "assumption that users perform better in a highly immersive VE," but the link between performance and presence is questionable. Frameworks such as VEPAB (Virtual Environment Performance Assessment Battery) (Lampton et al. 1994) and VRMAT (Virtual Reality Manipulation Assessment Testbed) (Poupyrev et al. 1997) were suggested to measure user performance in VEs. Nash et al. (2000) proposed several measures of performance that can be bridged to presence. Stanney et al. (2002) denoted that users who reported higher sense of presence were more efficient and effective in completing tasks. Youngblut and Huie (2003) found a positive correlation between the learning of mission procedures and presence. On the contrary, recent studies (see Cooper et al. 2018) report negative or insignificant correlation between performance measures and presence.

Presence is associated with eye-related (e.g., Jordan and Slater 2009), brain-related (see Clemente et al. 2014), heart-related (Egan et al. 2016; Meehan et al. 2005), and psychophysiological measures as well as physiological indicators of emotional response such as electrodermal activity (EDA) (Meehan et al. 2005) and muscular responses measured via electromyography (Antley and Slater 2011; see Kivikangas et al. 2011).

Preserving the Collective Memory and Re-creating Identity Through Animation

Inma Carpe
The Animation Workshop, VIA University College, Viborg, Denmark
Polytechnic University of Valencia, Valencia, Spain

Synonyms

Animation; Cultural identity; Memory; Self narrative

Definitions

Narrative identity	It is a person's internalized and evolving life story, integrating the reconstructed past and imagined future to provide life with some degree of unity and purpose.
The self	The self is an *experience*, not a conception. We can formulate the experience, more or less, in a conception; *but it is an experience*.
Collective memory	Collective memories are shared representations of a group's past based on a common identity. They are shaped by, and transmitted through, narratives.
Inquiry-based learning	Inquiry-based learning is often described as a cycle or a spiral, in which there are stages of question formulation, investigation, creation of a solution or an appropriate response, discussion, and reflection in connection with results.

Introduction

> *Knowing others is wisdom. Knowing the self is enlightenment. Mastering others requires force. Mastering the self requires strength*. Lao Tzu, (Tao Te Ching)

Philosophy has always been in charge of questioning great dilemmas of the human psyche and its existence, leaving to sciences the body's affairs. Aristotle, Nietzsche, C. Jung, and William James, among others, have tried to define the essence of the self; Roberto Assagioli – father of Psychosynthesis (2019), the psychology of the Self – defined it as an experience, which happens through introspection in an environment of empathy and love (Firman and Gila 2007). Working with animation aids to create such an environment, a socio-emotional learning space to work movies as open dialogs, an opportunity for self-introspection a research identity process (Moen 2006) through character design and animation. Without entering into a deep Cartesian or metaphysical debate about identity, we are closer to gain a better understanding of the self and what consciousness might be. We, our self, build reality from what we have learned, through our senses, making stories that become our memories and vice versa, memories that become our story – our narrative identity – and/or mental movies that shape our lives.

> Our memories are prejudiced, in the full sense of the term, by our past history and beliefs. Perfectly faithful memory is a myth, applicable only to trivial objects. The notion that the brain ever holds anything like an isolated "memory of the object" seems untenable. The brain holds a memory of what went on during an interaction, and the interaction importantly includes our own past, and often the past of our biological species and of our culture. (A. Damasio, 2010)

Our memory is fragile and influenced already by the unconscious past history of our genes (epigenetics); thus the emerging media platforms and manipulated information on the Internet "has altered the possibilities of memory recall and input across the globe: moments in time can be recorded, stored, then 'brought back to life, restaged, or replayed'" (Winter 2012, p. 4 cited by U. Linke 2015), making difficult to recognize what is true, and in occasions where the original story comes from. This demands skills for self-inquiry to develop critical thinking in order to question our present situations and past heritage, moreover to decide who we want to be as individuals and communities, as well as what is worth to preserve. It's important to give learners the skills to face challenges and become the directors-creators of their own story, hence be empowered to speak up to transform their lives (Zipes 2004). Social emotional learning takes into account relationships and these aspects; it's a holistic approach similar to the indigenous social narratives, which integrate body, mind, heart and spirit (Dunn 2019). Visual storytelling offers a medium to see, to explore our identity by questioning and reflecting about the knowledge and informative sources that shape our minds spirits, and relationships with each other as with nature.

> Animation is a representational strategy that is particularly suited to documentaries that explore fragmented pasts of forgotten, perplexing, yet often formative memories. The use of animation can emphasize that history and, importantly, memory, are ephemeral and can be a means to counter official and written histories. (Honess 2013)

We share stories from one generation to another, creating collective memories which can be distorted, or bias, depending on the writer/s perspective, context, and integrity (Coser 1992). We participated on cross-cultural projects working on animation as a means of mindful communication (and self-awareness) to preserve collective memory and identity from the artistic perspective of the creative process of visual storytelling (Chin 2004). In Europe, programs, such as the *Creative Learning and Animation* exchange, developed projects to facilitate the integration and adaptation of foreigners, including sensitive work with war refugees; *The Dressmaker, remnants of a life* (Fig. 1) (Carpe 2013) is a short film based on memory loss, where the author used storytelling to recollect some of her family's memories and grandmother's who suffered Alzheimer, questioning what makes the self studying how sharing stories affect our brain and well being (Reed 2014). The animation department of the Polytechnic University of Valencia, Spain, is producing exhibitions, *Animation to transform the World* (Las Naves 2018), and projects for LGTB to raise awareness of disadvantaged people and undermine communities; in Asia, *Animator in Paradise* (Fig. 2) (2016) has conducted several workshops with children,

Preserving the Collective Memory and Re-creating Identity Through Animation, Fig. 1 Textile art. The Dressmaker, Re-Construction of the Self

educators, and artists who wanted to see their community – Otsuki (Animanoiroha 2016) – reflected on local stories from the country side of Japan; in Africa, *Afro Games* (Chapon 2013) was a pilot developed as a TV series by artists from Burkina Faso who wanted to create original content depicting their childhood memories and African culture; in America, audiovisual projects like Amarath (Fig. 3) in Perú, institutions like Docu Perú, TAFA (ambulant workshop of audiovisual training), and TIFA Andina (2017), are working to create and recollect people's voices and myths from native communities; at the same time they use and teach their native languages. These are learning, multicultural and intergenerational projects, which share a common ground; to tell the stories from the protagonists' unique perspective; to heal, to educate and share them as they become visible.

> Narrative identity reconstructs the autobiographical past and imagines the future in such a way to provide a person's life with some degree of unity, purpose, and meaning. Thus, a person's life story synthesizes episodic memories with envisioned goals, creating a coherent account of identity in time. (McAdams and McLean 2013)

Why Animation

Currently it's not very common to conceive animation as a communication media of biographies. Nevertheless, features, as *Drawn from Memory* (1995, Paul Fierlinger), *Waltz with Bashir* (2008, Ari Folman), *It's Such a Beautiful Day* (2012, Don Hertzfeldt), *Wrinkles* (2012, Ignacio Ferreras), and *Rocks in My Pockets* (2014, Signe Baumane), are clear samples of the treatment of the autobiographic memory and narrative identity through animation documentary techniques.

When we produce (and watch) an animated film, we can appreciate how the creation of characters and scenarios become visual metaphors, making possible to visually feel one character's experiences, this is cinematic empathy (Gal & Hendler 2011). We experience, thanks to empathy, imagination, and complex cognitive processes, new virtual situations, which help us to reflect upon thoughts, feelings, and actions, which will build our best movie and legacy: our story life animated. "Our memory is our coherence, our reason, our action, our feelings. Without it, we're nothing" (Buñuel 1983).

P

Aristotle defined the Greek word psyche with anima or soul: the principle of life or principle of animation (De Anima, 1987). In time this definition has become more complex and goes beyond the anima, mind, or consciousness. The Greek philosopher considered all forms of poetry modes of imitation or mimesis; animation is mimesis; it can recreate past, present, or future life events as animated "storied lives." Rosemary Rich stated that "it is suggested that individuals construct continuous, ever changing narratives to produce coherent narratives of self – for which Sarbin coined the term 'storied lives'" (2014).

Animation for its power of abstraction and playfulness results in a very attractive and effective media to explore different perspectives and stereotypes (Batkin 2017) to work the neuroplasticity, facilitator of the physical changes of our brain, in order to keep learning within a contemplative context. We learn by listening, watching, and creating stories, real or fiction; they are individual and collective memories. They're visual testimonies, stories that connect us (Gowin 2011), legacies of artistic, historical, educative and therapeutic values (Crothers 2015), which can be preserved through the animation cinema as re-creations of our own identity, as part of the big collective consciousness.

From the beginning of humanity, we can appreciate in the caverns of Altamira the first testimonies of the Paleolithic men. These drawings are samples of animated representations about "the idea" of what hunting looked like or which kind of animals lived at the time. They are memories, printed on painted walls, impregnated with collective identities (Francis Steen 2014). These cave paintings are visual stories – collective memory – of an experience and perception of the reality from that specific period and individuals. Over time we may have changed formats and canvases, but those testimonies are not different from the ones told by Winsor McCay's in T*he Sinking of the Lusitania* (1918), the first animated documentary *Persepolis*, by Marjane Satrapi (2000) or *Ryan* by Chris Landreth (2004). The use of metaphors and symbols as a visual language provides the possibility of using animation to explain concepts of great abstraction and cognitive difficulty, facilitating the access of information to all types of audiences, including groups with lower education. Animation is an artistic expression of emotional energy in movement, a deep reflection that may bring to consciousness the subconscious as a contemplative practice, depending on how the creative process is conducted. Artists from different fields, like Tom Margett (2019), are finding in animation a playground to express memories and personal views; nevertheless one of the greatest potential of animation is being a multidisciplinary medium that provides a platform to the voices that need to speak out and people who need to be seen. "We are lucky to be in the position to tell our stories and we should never take that for granted" (Cusack 2018 cited by T. Margett 2019).

Methodology

From our perspective as lifelong learning artists/educators, animation cinema is a very intuitive language to learn and teach how we are in constant transformation, re-creating the self as our brain collects and edits our memories. During the creative process of a movie, students acquire basic knowledge of the brain functions and the cognitive processes involved to receive, decode, and store information – along with the film language and emotional literacy – to express ideas and feelings within their story. The integration of neurosciences within filmmaking enters the field of Neuroeducation, coined by F. Mora (2013).

It's the brain, together with the mind, the true factory of illusions, our "home cinema," the machinery that processes the thoughts created by the experiences and memories that constitute the personal story and narrative identity (Miller 2010, 2014). The narration that we create every day, shapes and defines our "being" (Daniel Dennet 1992). Nevertheless the brain is plastic, changes and evolves with each learning experience (Davidson 2012); hence understanding our mind is to comprehend our self/others and history.

One of the great similarities between artists, poets, and writers is the ability to link different elements that have no relationship through metaphors. This is one of the primitive forms of the brain that has to extrapolate the common factor

of different concepts and relate them to create new patterns (Ramachandran 2012); this brings us to consider animation a primitive and intuitive means of abstract communication and self-reflection. By understanding how we create stories and movies, students/artists have a media to develop critical thinking, creative learning, and self awareness, becoming the observer and creator of their own story (Hall and Du Gay 1996). Animation offers an opportunity to explore their history and culture to reevaluate values and traditions as they connect with each other. "Learning through aesthetics-in which cinema is included – stimulates a reflective attitude in the learner" (González Blasco and Moreto 2012).

On the projects previously mentioned, inquiry-based learning (IBL), which is socio-constructivist (based mainly on Vygotskian ideas), was implemented as a structure for the work flow adapted to the length and context of each project, from 2 weeks to 6 months of working with children, educators, animators, anthropologists, filmmakers, musicians, and drama teachers as guides. The focus remained on the process despite of the craft level that the final movies would reach. The reflecting phase on the process includes the steps of planning, retrieving, processing, creating, sharing, and evaluating, which are related to areas of affective and cognitive domains of metacognition (Alberta Learning 2004). To reinforce contemplation, drama and music exercises took place as mindful practices during the whole project. The phases of IBL, planning, retrieving, and processing, correlate to preproduction in cinematography; students work in groups – also individually – planning the work, researching ideas based on fieldwork to find the projects' themes and develop a brief synapsis with a storyboard. The creative phase corresponds to production, once the theme is chosen and discussed; different tasks are split among the group to start the animation, which finishes with postproduction. After the movie is rendered, it's shared and evaluated by the whole group. The main technique used was stop motion and mix of media to use our senses and work different materials.

Because animators embody the sensations and thoughts from their characters, the experiential process brings self-awareness opening the mind-heart.

> We remember in different ways at different times: the same memories can be recalled voluntarily, and resurface involuntarily. Moments of the past can be invoked by words, smells, tastes, and sounds: we represent these moments to ourselves in visual images, in stories, in conversations. (King 2000, p. 9)

In the construction of stories, the characters and spaces occur within a structure: a beginning, middle, and end. The animated narrative shows how our brain is prone to predict and seek for stability and continuum, learning to deal with stress and decision-making. Memories are the continuation of our narrative identity and history; animation cinema can be an innovative carrier of the emerging memories and past ones, by adding new insights that may help to avoid future tragedies.

> Tragedy is essentially an imitation not of persons but of action and life, of happiness and misery. All human happiness or misery takes the form of action; the end for which we live is a certain kind of activity, not a quality. Character gives us qualities, but it is in our actions – what we do – that we are happy or the reverse – a tragedy is impossible without action, but there may be one without Character. (Aristotle, 347–342 B.C.)

Conclusion and Discussion

Our self-created narrative identity is in constant evolution as we change, so our collective memory may suffer alterations due to bias, context, or time affects. The creative process of a film allows gaining deep insight to question our past history and present life in order to envision a better future as we become more present and balanced towards equanimity (Smalley and Winston 2010).

The results below are the common factors observed from the experiences working with teachers, artists, and students of different ages, ethnic groups, professions, nationalities, and sociocultural background during the international projects conducted in the last 10 years.

- Increase of self-awareness among the study group and its individuals and growth of connectedness
- Improvement in verbal and nonverbal communication

- Greater resilience and tolerance against other perspectives
- Identification of emotions and better understanding of feelings
- Increase feeling of democracy and cooperation
- Improvement in listening, empathy, and compassion (development of soft values)
- Acquisition of basic level of visual and cinematographic language
- Feeling of comfort or relief by sharing stories
- Rise of self-esteem and security when speaking in front of an audience
- Bigger appreciation of our heritage and personal background
- Arousal of curiosity and learning desire

Animation provides a rich variety of techniques to express and research deeper the psychology of the self and the reconstruction of experiences and memories as valid testimonies for cultural, educational, and health purposes, in the same way they entertain an audience. Visual storytelling has a strong potential to become a contemplative practice to promote cultural heritage (UN 2019), introspection, and well-being.

2D game; Game editor; Game level design

Definition

Most modern people are very attached to gadgets and devices in daily life. There are some people that spend most of their time playing video games. Sometimes, one may think to learn to create a video game. Before jumping into the game development area, a beginner needs to know basic knowledge and the basic principle of creating games. For the first-timer, it is better to learn to develop a 2D game for the first attempt since it is the simplest type of game to develop. The entry is a reference work to explore the basic principle of creating a 2D game level editor.

Introduction

Nowadays, many people are concerned about producing a game level editor without required programming. According to Chover et al. (2020), a game engine is designed in order to simplify the development of 2D video games. Al-Najdawi (2007) also stated that a game engine simplifies game development. Unlike game engines, the level editor is only being used as a tool for designing game level but still have the same purpose of simplifying the development of games. In addition, Vaca-Cárdenas et al. (2015) has agreed for the game level editor to enable user associate command to a game object only by dragging command block. Since the games have become an addiction, some people, especially gamers, enthusiasts, are to develop games for satisfaction even though having no knowledge of game development. Researchers recently focused on developing game level editors that are user-friendly for beginners (Aixinjueluo 2021).

Among existing 2D games developed, features like scrolling and spawning enemies are applied. One of the scrolling techniques used frequently is parallax scrolling. In parallax scrolling, farther planes move at a slower rate past the camera than the nearer plane to create an illusion of depth in a 2D scene (Balkan et al. 2003). Adding scrolling in game development has consequences, especially toward the enemies. At some point, enemies run out from the stage, and respawning needs to be set up (Silva and Sedlak 2008).

Among gamers, the term respawn refers to returning to life (Milburn 2018). In the current game, the developer wants the enemies to wait and be invincible until they spawn.

The foreground layer is the closest layer to the observer that use to attract the player's attention (Totten 2019). Many games do not use a technique like adding layers to the foreground layers because it reduces the clearness of the game, especially during parallax scrolling effects because gameplay elements need to be clearly visible (Broms 2021; Romero and Sewell 2019). Diving into coding is needed to ensure the object renderer is visible by the camera. This issue needs to be avoided while developing a game using a level editor without required programming. This is because Cowan and Kapralos (2011) stated that a level editor allows faster iteration times, designing levels visually and require low technical skill for designers.

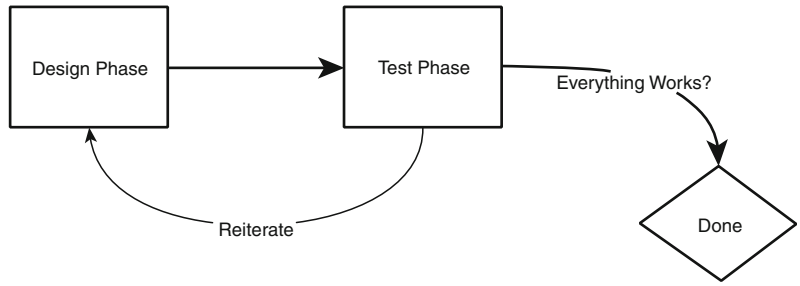
Game Level Editor

A game level editor refers to the program allowing the user to design computer game's environments and may be part of internal software development that can be used only by game designers or may be made as an open-source. Ng et al. (2018) indicated that level editors allow users to customize game levels and their content within a given video game. The roles of the level editor include elements of gameplay, environment, and sophistication of the graphics. Figure 1 shows a simple process of level design using a game level editor that allows the movement between the design and test phase easily. According to Smith et al. (2008), the reason for using the level editor is to make level designing much less technical and allow quick iterations.

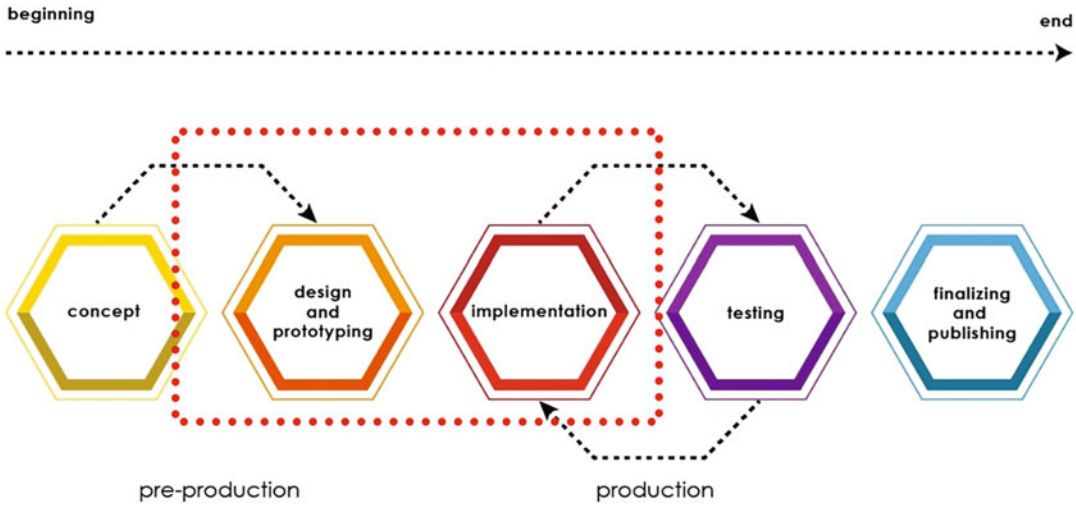
To develop a level editor for a 2D platformer, one must know the things that need to be included in the game level. Felgo (2021) previously suggested a model for platformer level needs to include several different components that can be categorized based on the purpose in the level, such as platforms, obstacles, collectable items, movement aids and triggers. Components of level editor depend on the needs of the game. So, a level editor needs to provide all required components to ensure the user can design the level for the related game.

The interesting part is the innovative systems and methods in a game level editor may give the opportunity for anyone with a young age or no programming experience and knowledge to use it. There are many ways to determine the features in a game level editor depending on its purpose. The most important feature for any game level editor is visualizing the level that means to allow its user to see the world that is being created while simultaneously enabling them to make modifications to it. According to this statement, this is because the user of the game level editor or level designer cannot create a good-looking world if the world's settings are in the editor and the game needs to be run separately by a different application.

The second thing that needs to be considered for the features in the game level editor is to integrate the level editor with the game. A tutorial made by Zhang (2016) had mentioned some important features that need to be tested while integrating level editor with the game. Those features include switching between editing mode and game mode, building level



Principle Structure to Create a 2D Game Level Editor, Fig. 1 Process of level design using the game level editor



Principle Structure to Create a 2D Game Level Editor, Fig. 2 General workflow process of game design

with obstacles, testing the levels, saving, and loading the level. The features must be fulfilled in a level editor to be fully integrated with the game that the user can edit. In addition, the features of the level editor must enable the user to customize the game level within the provided game (Ng et al. 2018). As discussed in the suggested model of platformer level by Felgo (2021), generally, the game needs to include platforms, obstacles, collectable items, movement aids and triggers. But for a 2D running game, it is just enough if the player can avoid enemies or obstacles and gain a score based on the running distance, as mentioned in Ferro and Sapio (2017). So, according to this statement, the features of the game level editor for a 2D running game must enable the user to make a change on player and obstacles or enemies.

A level editor for a platformer such as it works for redesigning a game level for a 2D platformer. Users can undo and redo the editing. Components involved in the game are the avatar, platforms, enemies, collectable items, and obstacles. The background of this game does not require scrolling. Players need to traverse the game to approach farther enemies. The enemies only move in a limited area and are invincible as long as the player does not jump on. This game level editor also provides setting to adjust speed, jump force, and else.

2D Game Design and Gameplay

Game design refers to the design and creativity used to develop games either for the purpose of entertainment or education. Game design usually comes up with game concepts. Game concepts are like an instruction book that becomes a guide for designers and developers to understand the vision of the game that wants to be developed by the team. The game development starts with game concepts that outline the features in-game, goals, and the entire gameplay.

Based on Fig. 2, Ferro and Sapio (2017) illustrate the general workflow process of game design. The preproduction process of game design started with the game concept and was followed by design and prototyping. The game production process involves implementations and testing. The game can be finalized and published after completing all the processes. Figure 3 has indicated the red box, which was in the process the level design might commonly involve. Based on Aaltonen (2018), the level design is one of the subgenres of game design because the design of the game level represents the player's experience in a game that involves interactions. The level design usually aims to satisfy and provide an entertaining experience to customers or users.

The game design is also concerned with game mechanics. Game mechanics refers to the

Principle Structure to Create a 2D Game Level Editor, Fig. 3 2D image usually used for changing background

procedures and rules that need to be followed by the player and the game in response to the player's actions. Apart from that, Winn (2009) and Sae-Lao et al. (2019) agree that game mechanics are formal rules that define operations in the game world, including players' actions, goals, and challenges.

Some game design requires a storyline or plot. Game design is the main theme in the game, including the storyline, plot, and back-stories of characters, but in smaller games and others that do not require significant character or plot like in some racing games, game design refers to the game mechanics.

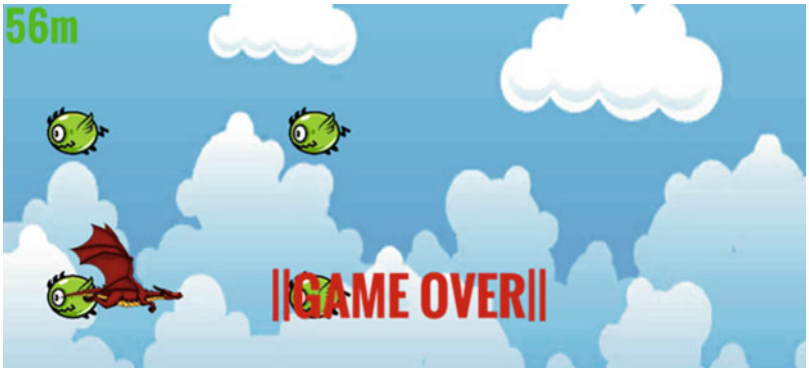
In the gameplay of an endless 2D platform game, two elements that play roles in the game are traps and coins (Fabricatore 2007). In the game, the player needs to move forward continuously to collect coins for scoring while avoiding obstacles that can lead to the game being over. According to Zhang (2016), the player starts running from the left to right side of the screen while avoiding enemies or obstacles by jumping and the highest score is recorded based on the running distance. A player only has one life, which means hitting one time on obstacles or enemies trigger the game to end, high score and current score directly recorded, same goes to the player falling into traps like gaps on the ground. Each gameplay has its own quality. A gameplay has become the key element to judge digital games's quality. The quality of gameplay can be determined by the balance between the level of challenge and the abilities of the player.

2D Game Level Editor Structure

The following sections are to elaborate on the steps involved in order to produce the user editing parts for the level specifications of the 2D game. This includes the elaboration of each different task and feature implemented in the level editor.

Changing Player and Background Sprite

The options to choose different sprites for the player's character to be used in the simple 2D game made we called a changing player. The player is the playable character provided in this game level editor to be played within the 2D running game. The player asset is using 2D sprite since the running game is developed in 2D. All the assets are converted in the form of Unity prefabs so that the scale and rotation of image sprites used can be preserved any time the user selects the asset to be used in the game. In the editing screen, a dropdown is used to display different options for the user to choose the desired character to play with. Only one character can be chosen at a time. Those go the same for the editing options of the background sprite. The selected option is shown in the preview screen provided before the user can proceed to the game scene. They are scrolling background scrolls infinitely during the game. The background sprite is set to that material. Then the material is added to a plane that acts as the mesh for the background. Figure 3 shows the examples of 2D backgrounds commonly used.



Principle Structure to Create a 2D Game Level Editor, Fig. 4 Game over in 2D game

Change Enemy's Pattern, Speed, and Spawn Delay

As for the enemy, this application provides options for the user to change and manipulate the spawn patterns, speed, and delay time. These different options play an important role in determining the difficulties of the game. The enemy pattern editing options allow user to choose two different types of patterns out of four by clicking on the corresponding checkbox that indicates each pattern. The difference between patterns is the formation and position of enemies while spawning to the game. For the speed, it is set for the user to choose from the range of one to ten. Meanwhile, the spawn delay of enemies can be chosen from range one to five.

As for scoring, the score is calculated based on the distance travelled by the player as long as not colliding with the enemies. The distance starts from zero and is set as incrementing by the float value of 0.2. Then, the distance is displayed as an integer in the text as a score during the game.

Enemies' behaviors that can be changed in this project include delay time to be spawned, movement speed, and the formation pattern for groups of enemies while spawning to the game. The enemy in the 2D game moves from out of the screen at the right side toward the player. The enemy can be considered as an obstacle for players to move forward.

The game is over, as, in Fig. 4, the condition is triggered after the player collides with an enemy, as explained early for the player's mechanics for this 2D running game. At the start of the game, the initial time is set as one to ensure the screen does not freeze, and the game over text is set as inactive. Meanwhile, if the player collides with the enemy, the game ends. Time is set as zero to freeze or pause the game screen, and the game over text is then set to active.

Import and Export Files

The editor provides options to import or export files that consist of the properties chosen by the player. There is an input field for the title of the game on the editing screen. The exported file is renamed as the title input by the user. The file is exported in the form of .txt format. Users then can import back the data saved in that file to the project.

While exporting a file, the saved file is named by the title and in .txt file format. To mention, the exporting and importing file in this project only supports the .txt file format. Users can click on the "save" button to save all related data that had been chosen in the editing scene and export it as a .txt file. The data saved are converted to either integer, float, or string in the file. To import the data from the edited 2D running game, the user can click on the "load" button to load the file and import all the data from it. Figure 5 shows the "load" and "save" buttons that are located at the bottom of the preview screen for the user to choose either to import or export data on a .txt file. Before going further to exporting or importing the file, there is an input field that requires the user to type a title. The input field for the title can be seen in Fig. 5.

Procedural Audio in Video Games

Matthew Yee-King and Igor Dall'Avanzi
Computing, Goldsmiths College, University of London, London, UK

Synonyms

Algorithmic composition; Automatic sound synthesis

Definitions

Procedural audio is a way of making sound and music for video games through the use of generative models which can algorithmically produce material such as sound effects and in-game music.

Introduction

The term procedural audio refers to the use of sound or music in video games that is not pre-sequenced or pre-recorded. Sound designers implement the audio assets as algorithms that generate sound during the game and which, unlike pre-recorded sounds and music, can be incrementally influenced by game data and events. For example, different layers of a musical piece might be combined in different ways depending on the game state or, at a lower level, the sound of a door opening might depend on the angular force applied to it.

Video games often offer a nonlinear experience dictated by the player's actions, and usually, these actions influence the soundtrack and sound effects (Collins (2008a)). Therefore the sound of most games is influenced by input from the player, even if only by which area of the game world they are in or when they fire a weapon (Collins (2009)). Changing the music according to the game level and triggering sounds when the player fires a weapon are not procedural audio though; these examples are missing the critical features of procedural audio systems which is the use of a generative model.

We use the term generative to refer to models utilizing algorithms to produce an output that is not explicitly defined. A simple example is writing several fragments of a musical score and then choosing the sequence in which the fragments are played back at random. Given enough fragments, this "musical dice game" might generate a different piece of music each time.

Farnell (2007) identified further properties that are commonly seen in procedural audio systems. The more relevant properties in the context of video games are:

- **Interactive**: Rowe defined "Interactive Music Systems" broadly as musical systems that change their behavior in response to user input (Rowe (1992)). Procedural audio expands the interaction to include other game objects and events that are not necessarily triggered by the player. The concept of interactivity is not limited to the use of input to trigger sounds but also to change the properties of the sound such as volume and pitch.
- **Nonlinear**: Nonlinear audio generators can move between a number of states in different orders, at different rates, and in different directions (Farnell (2007)). Most musical instruments are examples of nonlinear audio generators, since multiple notes can be performed at the same time in any order. This flexibility helps to create models with complex behaviors able to

adapt to the range of different dynamic scenarios typically present in video games.

- **Adaptive**: Adaptive audio changes according to a changing game or player state (Farnell (2007); Collins (2008a)). For example, if a player is running out of health points, the music might become more discordant to increase tension. This is different from the interactive concept, as the sounds are not so directly influenced by player actions. Despite this distinction, Collins groups interactive and adaptive sound under the term "dynamic audio" (Collins (2008a)).

To summarize, a procedural audio model is generative and uses algorithms to create its output. When programmed in a nonlinear fashion, it can adjust its sound to respond more or less directly (interactively or adaptively) to player input, game events, and game state.

Advantages of Procedural Audio for Game Development

Using models to generate and control sound leads to several advantages.

- **Variation**: In procedural audio, a single model can generate a vast range of different sounds or music through the modification of its parameters. It is not necessary for the composer or sound designer to specify every possible variation. There is an analogy between the evolution of the graphics used in video games and the difference between traditional and procedural audio. Graphics have evolved from simple, sprite-based animation through to 3D models with textures and lighting. 2D sprites define every possible rendering of a game character beforehand, but 3D models are rendered and lit in real-time depending on the position and orientation of the camera and the character, leading to a massive space of possible outputs from the basic models.
- **Efficiency**: Since a single model can generate a vast range of outputs, it is not necessary to use RAM resources to store a large set of pre-rendered sounds. If the model uses pure synthesis, it can take up kilobytes of RAM instead of megabytes. However, the procedural model might require greater CPU resources to execute than a pre-rendered sound player.
- **Coherence**. Using game data to influence the generation of sound and music allows for a deeper and more realistic response to game events. Force vectors can be used to control an impact sound, not only by using a volume control but, for example, adding harmonics or layers to it as the intensity of the hit grows. The interaction between different game objects can be handled automatically, using procedural audio models that receive information about the shape, materials, or movement of the objects impacting them. Duration or style of sounds and music is no longer predetermined but adapts to the nonlinearity of game events, leading to better synchronization and coherence.
- **Modularity**. Procedural audio models can be designed to exchange control data or sound in a modular fashion. In this way, they can be reused or combined differently for different contexts. For example, a procedural animal noise generator can make sounds for several different animals.

Challenges Preventing Broader Adoption of Procedural Audio

Despite the advantages listed above, the games industry rarely adopts procedural audio (Böttcher (2013); Hamilton (2015)). Some of the major factors preventing more extensive use of these models are listed below.

Lack of Tools, Skills, and Time

Building procedural audio models is a complex task that requires knowledge of a wide range of disciplines including programming, synthesis, physical modeling, acoustics, mathematics, and probability theory.

Developing the prototypical model requires an understanding of the desired sonic behavior and tools to translate this behavior into sound. Flow-

based languages for audio like *Pure Data* (Puckette et al. (1996)) or *Max MSP* (Puckette and Zicarelli (1990)) are appropriate for the task (Farnell (2007); Hamilton (2015)) but the development process involves programming and is very different from the traditional sound design workflow.

Even if the sound designer is prepared to use tools such as Pure Data, the target game engine might not integrate well with the tools. Notable developments in this area include the heavy engine by Enzien audio and libPD (Brinkmann et al. (2011)), which allow Pure Data patches to integrate more easily with game engines.

Sound Quality

There are several aspects to sound quality that we will consider here: the realism or perceived quality of sound effects, the musicality of generated soundtracks, and the perceived quality of playback systems for generated soundtracks.

Procedural sound effect synthesis is commonly seen in the games industry as taking more time to develop sounds of a lower-quality than pre-rendered assets (Böttcher (2013); Somberg (2016)). This preconception might be related to the skill requirements and the lack of tools discussed in the previous section rather than to procedural audio itself – a recent perceptual study evaluating synthesized sound effects suggests in fact that sound synthesis can be as convincing as recorded audio samples if the appropriate methodology is adopted (Moffat and Reiss (2018)).

Attaining high musicality in generated scores is a significant challenge in the research field of algorithmic music, especially concerning long-term structure. Current systems cannot compete with the musicality of handcrafted, fixed compositions, despite recent advances in specific areas (Hadjeres et al. (2016)). The evaluation of generative music systems is a complex topic (Collins (2008b)), but Peter Langston, audio programmer for the video game *Ballblazer* (Activision, 1984), gave a simple rule. The game featured one of the first generative music systems heard in a video game. For Langston, procedural music has to pass a "is it interesting music?" test, to be considered successful (Langston (1986)).

Once the system has generated a piece of music in the form of a note sequence or score, the score must somehow be rendered on the fly into audio. This rendering can be done with a MIDI sound bank or with a more elaborate synthesis engine, both of which require more resources than simple audio playback. To put this in context, a precomposed, pre-rendered musical score can be played by a real symphony orchestra, and playback of the recording would only involve a single audio track.

CPU Resources

The adoption of procedural audio leads to increased, but variable, use of CPU resources. Computational cost, in particular, is one of the main arguments contending toward the adoption of these models. However, in a series of interviews run by Böttcher (2013), different academics, audio directors, and programmers confirmed that elements like oscillators or filters could fit the memory constraints of current game audio development (around 5–10% of the total CPU budget). The problem, they outline, is more in the lack of tools and in the change of workflow that adopting procedural audio comports. An example of how issues of efficiency and accessibility were faced is found in the proprietary procedural audio tool developed for Grand Theft Auto V (Rockstar Games, 2013), which we will discuss in the following section.

Applications of Procedural Audio in Video Games

This section describes some state of the art and historically relevant examples of procedural audio systems for music and sound design found in video games.

Music

Ballblazer: The Riffology System

As already mentioned, the menu theme of the game *Ballblazer* (Activision, 1984) is one of the earliest examples of the use of generative music in video games. The system, called *Riffology* and designed by Peter Langston at Lucas Arts, dynamically combines different music segments (riffs),

using a system of weighted random choices. These control elements such as the choice of the riff to play or how to play it: how fast, loud, or if skipping any section inside a musical part. Created to model a "lazy guitarist," the system makes choices both randomly and also by looking at elements like the note distance between different riffs (Langston (1986)). Langston describes the music generated by the system as passing the "is it music?" test but failing the "is it interesting music?" one, due to boring rhythmic and melodic structures that makes it difficult to listen closely for more than 10 min.

Spore

Electronic Arts' *Spore* (2008) is a video game about evolution. The player is asked to direct the evolutionary path of a species, from bacteria in the primordial soup to an interplanetary civilization. The game features an editor in which the user can tailor their creatures for survival. Later in the game, elements like vehicles and spaceships can also be designed. The editor is a key element of the game and one where users could spend much time. To make long sessions enjoyable and to enhance player retention, the developers implemented a generative system for the editor's music (Jolly and McLeran (2008)). The procedural model was developed in Pure Data by audio programmers Kent Jolly and Aaron McLeran, in collaboration with composer Brian Eno. The system consists of two parts – a percussion pattern generator based on different random seeds and a melodic section that works by combining short samples of music. The system alternates intense and calm moments, avoiding repetitive melodies to maintain musical interest over longer play sessions. Moreover, the music changes dynamically according to the player's choices in creature design. If they create a predator, primitive tribal drum patterns will be triggered. Building futuristic vehicles like spaceships later in the game will lead to more synthesized patterns.

Rise of the Tomb Raider: The Dynamic Percussion System

The *Dynamic Percussion System* used in *Rise of the Tomb Raider* (Square Enix, 2015) generates percussion patterns in real-time. It aims to address problems of quality, interest, and accessibility typical of procedural music. MIDI percussion patterns were provided by the composer to be analyzed by the system. The software is then able to generate variations of these patterns of different intensity in real-time. These variations are associated with game states so that during the game the system can dynamically move between them following the action in the game (Lamperski and Tahouri (2016)).

Sound Design

No Man's Sky: The Vocalien System

No Man's Sky (Hello Games, 2015) is an exploratory game where the player moves in a procedurally generated universe. A synthesis system was used to give voice to the fauna that populates the different planets, as it was impossible to know the beasts' traits beforehand during game development and to create appropriate assets for them (Weir (2017)). The system, called *Vocalien*, consists of different oscillators and filters and uses the physical traits of the animals as well as their states (like hunger or aggressive/calm behavior) to generate their voices. It is an example of how procedural systems can be used to defer decisions until runtime and to connect behavior and state to sounds.

Procedural Audio in Grand Theft Auto V

Audio programmers at Rockstar designed a dedicated procedural audio tool for the company's proprietary engine and used it in the development of Grand Theft Auto V (MacGregor (2014)). The system is characterized by a node-based user interface, with an emphasis on real-time visualization of audio and control data to make the system more accessible to sound designers. The developers used the engine for sounds like door slams, metallic impacts, and air conditioners and vents. The system was especially useful for the generation of noisy sounds which can suffer from unwanted artifacts after being encoded to compressed file formats.

Conclusion

Procedural audio is a method of producing sound effects and music for video games which makes use of generative models instead of fixed audio

assets. Procedural audio always makes use of algorithmic processes to generate sound, but it can also be interactive, nonlinear, and adaptive. Procedural audio has several advantages over the fixed asset approach: the audio is more varied, it can be more efficient, it can provide a more coherent experience, and it provides modular, reusable audio assets. Procedural audio faces several challenges to its broader adoption – it demands a different and more extensive skillset than fixed asset production, it can be difficult to match the sound quality of fixed assets, and it has a different computational resource profile. Game developers have used procedural audio to generate music and sound effects in games for many years, including high-profile titles. Such as Tomb Raider and Grand Theft Auto.

Definition

Call of Duty	A first person shooter that is published by Activision
e-Sports	A multiplayer competition that is played using video games
Fortnite	A free online battle royale game developed by Epic Games
League of Legends	A multiplayer online battle arena game developed and published by Riot Games
Valorant	A free to play hero shooter developed and released by Riot Games

Introduction

This entry examines the professional career of the former "Call of Duty" professional player Matthew "Nadeshot" Haag. This includes his career as a professional Call of Duty player, his career after retirement from the Call of Duty competitive scene, and the foundation of his e-sports organization "100 Thieves." This entry talks about his achievements and the influence that 100 Thieves has created in the world of e-sports.

Professional Career

Matthew Haag played most of his professional career for OpTic Gaming, one of the biggest organizations in "Call of Duty" with one of the largest fan bases in the entire "Call of Duty" e-sports scene. In 2011, Haag and his team won Call of Duty XP. This was "the first ever Call of Duty fan experience" (Activision n.d.) held by Activision with a prize pool of 1 million dollars. In 2013, his team earned third place in the Call of Duty Championship. The championship is held once a year, and it could be compared to big sports championships like the Super Bowl or the World Series. In 2014, Haag and his team won the MLG X Games Invitational. This tournament "was the first event to feature Call of Duty highlights on national television and the first e-sports event to award X Games Medals" (MLG X Games n.d.). Following the release of Call of Duty Advanced Warfare, Haag and his team went on to win 17 first place finishes out of 29 tournaments. The track record was impressive, until in an unexpected turn of events, Haag and his team were placed seventh at the Call of Duty Championships. This led to Haag announcing his retirement on April 4, 2015, as he believed that he was no longer capable of playing at a level that would not hold his teammates back.

100 Thieves Creation

After Haag's retirement, he went on to found 100 Thieves in 2017. Haag cofounded 100 Thieves with Cleveland Cavaliers owner Dan Gilbert. Since the creation of 100 Thieves, they have "raised $60 M from investor including Drake, Scooter Braun, Cleveland Cavaliers Owner & Quicken Loans Chairman Dan Gilbert, Artist Capital Management, Ludlow Ventures, Green Bay Ventures, and Sequoia" (About Us n.d.). Haag is the founder and CEO of the organization to "lead the company's creative, brand, and strategic direction" (About Us n.d.). In April 2021, it announced that popular content creators Rachell "Valkyrae" Hofstetter and Jack "CouRage" Dunlop (Waananen 2021) would become co-owners of 100 Thieves.

100 Thieves Influence

100 Thieves is an entertainment, gaming, and apparel organization. They have created multiple

competitive teams for e-sports games such as League of Legends, League of Legends Academy, Fortnite, Call of Duty, and Valorant. 100 Thieves has also created an amateur League of Legends team called 100 Next to "assist younger players new to the competitive scene" (100 Thieves Next n.d.). These teams have "won multiple major championships" (About Us n.d.) during the first 2 years of the organization's life. Along with the teams' competitive teams, they have signed multiple popular content creators, including BrookeAB, Classify, CourageJD, NoahJ456, Valkyrae, and many more (Teams n.d.). 100 Thieves sells apparel, which has sold out on 12 different apparel drops. They also "launched the top gaming podcast on iTunes" (About Us n.d.). Another contribution they have made is opening up the players' training facility in California for use as a vote center for the 2020 United States presidential election.

Conclusion and Discussion

Matthew "Nadeshot" Haag had a very successful professional Call of Duty career.

Winning multiple tournaments with OpTic Gaming includes one of four of the first X Games Gold Medals to be awarded for an e-sport competition at the X Games. After his retirement, Haag has become successful as the co-founder of 100 Thieves. 100 Thieves has undoubtedly become one of the most influential organizations in e-sports and entertainment. Haag exemplifies a successful transition from being a professional gamer to an e-sports entrepreneur.

Definition

Covid-19 has become a global health crisis in the year 2020 that has brought the entire world on a standstill. The title "Protection Korona" is the name of a game designed on Covid-19 to help impact and educate people to protect themselves while learning about ways to remain safe and healthy.

Introduction

Covid-19 has brought the world on the edge with its uncontrolled spread. People are unaware of facts and are hence formulating their solutions with half-knowledge about the pandemic, thereby inducing an atmosphere of fear. This entry will talk about how we can use games as a medium to solve this problem of people not knowing about the pandemic. This entry will take "Protection Korona," a game designed on Covid-19, as an example to explain how game design can be a great solution to tackle social problems easily and interactively that would make the people want to engage in willingly. This entry will also touch upon the three main areas that you need to have an understanding of while designing a game to tackle is a serious problem.

A Touch upon the History of Games

Games have been known to have existed for more than 9000 years. These include sports, play as well as board games. Even though tabletop games can be traced back to ancient times, not all of these games were designed by a designer but rather came into being and were then developed and improved according to the folk process and modern times. Today many of these traditional games have been commercialized to fit the interest of the people and are used widely. Thus, games have been a part of the human race for a long time and have been a part of every individual's life at a point in time.

Game Design as a Solution

Wikipedia defines game design as the "art of applying design and aesthetics to create a game for entertainment or for educational, exercise, or experimental purposes." While this is correct in technical terms, game design can also be interpreted as the art of creating experiences that are fun, and that makes you indulge in activities that help to exercise your brain. Games are a great way to engage people and research shows that people are more inclined toward interactive ways of learning rather than theoretical versions that give you only information and no entertainment. Games create curiosity and act as a drug for learning.

Games are a great way to engage the young generation as well as older people and act as an easy and effective way of introducing essential cognitive skills in them. They not only help you with decision-making but also act as a bridge between knowledge and its application. They

make you curious and thereby help you learn things that you wouldn't otherwise. They give you a platform to make mistakes and solve them which gives you a practical approach and thereby helps you to remember these learnings. As playful animals, we love to create, cocreate, construct, and deconstruct our "real" world through gaming (Kriz 2020). This characteristic of humans is what can be used as a way to educate them about the things that they ignore otherwise. Games are a great solution to make people aware of the problems and issues around, in an easy and lighter way making sure that it is not misinterpreted.

Times of Covid-19

As we know, 2020 is facing the pandemic of Covid-19 and has brought the entire world on a standstill. People are dying around every day and news and media are creating fear in the minds of the people so much so that people are finding it easy to believe in misconceptions than to find facts about the pandemic.

During this time of pandemic, there has been an increase in people indulging in games as a past time. There are many games that deal with the topic of pandemics. These games are usually a hybrid mixture of entertainment and educational games. They help people to understand complex situations and how to deal with them while having fun and keeping positive. They invoke a sense of responsibility in people and hence indirectly make them aware of the problem.

One such example (See Fig. 1) of a game on Covid-19 is "Protection Korona" which is a board game designed to tackle the lack of awareness in the people about the pandemic as well as sensitize them toward taking actions and do their part to remain protected and safe. This entry will further highlight how the game has acted to be a good solution and how it affects the players.

Protection Korona

The board game is designed to have four main character roles that the players can play as which are doctor, police, researcher, and public. Having roles in the game helps the players to emotionally connect with their character and also understand their role in real life, thereby making them a little sensitive each time they play or act on their role duties. The goal of the game is that the first person to cross all the four parts of the board and reach back to where they started without getting affected

Image source – Created with Adobe Illustrator

Protection Korona: A Game Design on Covid-19, Fig. 1 A board game's visual design

wins the game. There are protection item cards that the players have to collect in order to remain safe and not get affected by the virus. The game's USP is that it allows you to trade your cards with the other players in order to help them in case they are to be affected. This characteristic feature of the game is to encourage the players to resort to unity and makes them understand the importance of playing and fighting the challenges of the pandemic together as a team.

Players have to face various challenges throughout the game and overcome them by making preinformed decisions. The board contains various tiles that have "health items" for boosting immunity, "virus tiles" that will infect the players, and "protection item tiles" that will give the player's protection equipment to collect and trade in order to remain immune to the game.

The game also has immunity booster scales that will update each time a player lands on an infected tile or a virus tile. This will help the players remain attentive throughout the game. The game also has quarantine and hospitalization zones that will educate the players as to when they need to do either of them. Each role that the player will play will give them a duty and role to play in the game. This will not only make them aware of the problems that these character roles (doctors, police, public, and researchers) face but will also help them to relate with them.

Being a family game with dimensions that are sufficiently big, the players will be sitting far apart from each other and will also be following the same social distancing norms as a part of the game. The game has been designed in such a way that the players will by the end of it know every small and relevant detail that they need to know about the pandemic and also how to help themselves and those around them by maintaining strict distancing.

The game will help the players to know about the importance of unity in these terrible times and will help them to develop respect and sensitivity toward these really hard-working characters of our society who are helping every day toward protecting the world and the people in it.

Conclusion

The testing of the game showed that people started to ask questions about what they had seen on the media and news channels about things that were fake and they appreciated the game for helping them learn the facts. The game that was curated based on the suggestions of the people also showed great changes in the way their mindset was about the different heroes of this pandemic. It's safe to say that the game proved to be a great solution to educate people about the pandemic and make them feel for those fighting out there to save the public every single day and to curb it. This leads us to think that perhaps games are a great and easy way to make people interested in knowing about topics that otherwise seem scary and too much to take.

In this era where people are tired of the information deliverables around them, games are a very innovative and interactive way to make them aware of the problems and also help them spend some quality time with their family while doing so.

Psychology in Game Design

Definition

Psychological game design is the use of psychological principles in game design to enhance player experience and engagement.

Introduction

Research on psychological aspects of digital games has been rising within the last decade. Game companies also started to hire psychologists to conduct research and implement psychological principles in their game designs. In this article, major psychological theories that are applied to game design are briefly introduced.

Operant Theory

Operant theory (Skinner 1953) mainly suggests that rewards motivate desired behaviors, and the frequency of a behavior depends on the schedule of the rewards. Rewards might be provided after a fixed number of behaviors (i.e., fixed ratio) or after a variable number of behaviors with an average ratio (i.e., variable ratio). Similarly, reward schedules might also be based on time intervals rather than the number of behaviors (interval schedules). In general, ratio schedules result in higher response rates than interval schedules, with variable ratio schedules resulting in the highest response rates.

These different types of schedules of reinforcement are one of the most frequently used elements of psychological game design (Lewis et al. 2012). Players engaging in repetitive and boring game activities merely to obtain a desired in-game reward (called "grinding" or "farming") that is provided on a variable ratio schedule, free to play games that require waiting for a fixed amount of time (a fixed interval schedule) unless the player pays money are some examples of the use of operant theory principles in game design (Uysal and Yildirim 2016). It should be noted that although such applications increase playing time by putting players in a Skinner box, they do not necessarily increase enjoyment. In contrast, these external motivators are more likely to have adverse effects on player's satisfaction and well-being (King and Delfabbro 2009; Przybylski et al. 2009).

Self-Determination Theory and Basic Psychological Needs

According to self-determination theory (Ryan and Deci 2017), people have three basic psychological needs. Autonomy refers to having choices and fully endorsing one's actions, competence refers to feeling effective and capable, and relatedness refers to feeling close and connected to others. Satisfaction of these needs is essential for psychological well-being.

The principles of basic need satisfaction have also been applied to game design. Studies show that games that satisfy autonomy by providing choices and freedom, competence by providing optimal challenge and clear feedback, and relatedness by providing a sense of connectedness to the game's digital world or player community are found to be more enjoyable and highly rated by players (Ryan et al. 2006). Several examples of the applications of basic need satisfaction in various genres of games are provided by Rigby and Ryan (2011).

Technology Acceptance Model

Technology acceptance model (Davis et al. 1989) is an application of the theory of planned behavior (Ajzen 1991) to the field of information systems. According to TAM, salient beliefs such as perceived ease of use and perceived usefulness of a system are the main factors that predict people's intentions to use a technology, which in turn predicts actual use.

Although TAM focuses on utilitarian systems, the model is also expanded to hedonic systems (Van der Heijden 2004). In hedonic systems, perceived ease of use was conceptualized as the primary antecedent of perceived enjoyment. Indeed, perceived usefulness could be less applicable to games as gamers are more focused on fun rather than utilitarian values of a game (Lowry et al. 2012). Nevertheless, the model introduces perceived ease of use, a factor that is closely related to game design elements, as an antecedent of enjoyment. Thus, game features that make the games more accessible to players and increase the games' ease of use are also likely to increase the player's enjoyment (Hsu and Lu 2004).

Social Cognitive Theory

According to social cognitive theory (Bandura 1986), people evaluate the expected outcomes of a behavior based on their observations and past experiences. These expectations, along with some other personal and environmental factors, play a key role in determining whether the person will engage in a behavior.

Focusing on the role of expectations, researchers applied SCT to games and identified some game design elements that fuel player engagement (Lee and Larose 2007). Accordingly, providing agency by allowing players to determine their own actions, presenting a believable and convincing narrative, setting achievable goals that result in a good performance, and allowing players to interact and socialize with other players are the main in-game elements that increase player engagement (De Grove et al. 2016).

Investment Model

Investment model (Rusbult 1983) is a relationship model, which identifies three independent factors that predict commitment to romantic relationships. Accordingly, satisfaction with the relationship, quality of alternatives to the relationship, and people's investment to their relationship are antecedents of relationship commitment. Thus, people might still be willing to continue their low satisfaction relationships, if they do not have alternatives to their relationships or if their investment in their relationships is high.

Similarly, game elements that increase players' investment in the game also increase their commitment to the game, independent of their satisfaction with the game (Uysal 2016). For instance, players of games with persistent virtual worlds

(e.g., MMOs) might have invested a considerable amount of time and effort to their virtual characters, which maintain their commitment to the game independent of their satisfaction levels. Similarly, game companies started to employ microtransactions more and more frequently in their games mainly to increase their revenue; however, these transactions are also increasing players' monetary investment in the game, resulting in greater player commitment.

Conclusion and Discussion

These studies show that the field of psychology provides a rich perspective for game design focused on enhancing player experience. Although exploitation of psychological research, especially external motivators, by game companies to increase profits also brings some ethical concerns (Søraker 2016), better-designed games that focus on intrinsic motivators would contribute positively to the well-being of players. Nevertheless, the field is relatively new and psychology has a lot more to offer (Bostan 2016) for understanding what makes games more enjoyable and fun.

Synonyms

Edutainment; Purposeful games; Serious games; Transformative games

Definitions

Purposeful games	These are games which have specific objectives besides entertainment, like providing new knowledge to the player on a specific topic or enhancing the usage of existing knowledge, or improving his/her motor skill, benefitting him/her directly, or using the player to serve some other purpose like generating data for machine learning using gameplay, e.g., a game may require a player to match products with customers and the player's answers may be used to train a computer program to perform this task automatically in the future. Though the player matching the products and customers may be paid, she/he may not get any intellectual benefits or improve motor skills.
Serious games	These are purposeful games intended to benefit the player directly by providing new knowledge or enhancing the usage of existing knowledge, or helping the player improve some motor skill, to change his/her thinking or behavior. The intended benefit may or may not be long-lasting, e.g., the benefit provided by a serious game intended to train a player to solve problems based on a topic in an optional academic course may be short-lived if the player is taking the course just to fulfill graduation requirements, but the impact of a game intended to teach safe driving may last lifelong.
Transformative games	These are serious games intended to directly provide a long-lasting benefit to the player by positively transforming his/her thinking or behavior, e.g., a game teaching the player to manage money or emotions or priorities or relationships with peers or storage space better is a transformative game.
Edutainment	It is an educational entertainment. Serious games provide edutainment.

Introduction

Educating the public about health via computer games is very important because not everybody can see qualified medical professionals due to temporal, spatial, or financial constraints. Also, some people find computer games more engaging than counseling, clinical visits, reading literature, or listening to lectures. Scalability and the ability to educate almost ubiquitously make carefully designed computer games very effective for reducing healthcare costs and supplementing traditional medical care. This entry is a short but comprehensive survey of implemented and evaluated computer games and game-like virtual environments intended to make people aware of health problems and their consequences, unhealthy

habits, and misconceptions about health and inspire them to take better care of themselves. The emphasis of the entry is on covering health problems addressed by computer games and not on covering all computer games addressing individual health problems.

Alcohol Consumption

Excessive alcohol consumption is known to have bad effects on brain, heart, liver, pancreas, and immune system and increase the risk for multiple kinds of cancer. Driving under the influence of alcohol jeopardizes drivers as well as passengers and is known to cause thousands of fatalities worldwide each year. Persons consuming alcohol excessively may cause physical/mental harm to others or break laws. CollegeLive (Hughes et al. 2016) is a virtual environment for letting users experience social interactions that are typically experienced by first-year college students. This environment is intended to promote prevention of drunk driving and sexual advances by/toward drunk people and rationally handling peer pressure leading to these behaviors.

Anxiety and Trauma

Above Water (Wehbe et al. 2016) is a game for educating players on generalized anxiety disorders and panic disorders. These disorders involve excessive worry or fear which is often irrational. Besides reducing productivity, they can be debilitating. Physical symptoms may accompany mental symptoms of these disorders. Above Water is a hybrid game because players play using electronic devices and physical cards about (i) life goals, (ii) anxiety, (iii) treatment, and (iv) sharing a strategy helping them or tips or a question. Some treatment cards activate an interactive experience using deep-breathing app or yoga-and-stretching app.

Witnessing natural disasters, violence, accidents, physical or mental abuse, or their effects can be traumatic. Cognitive behavioral therapy (CBT) is a widely used drug-free paradigm for minimizing the impact of such trauma. The game in (Assigana et al. 2014) is for educating children on CBT. Children playing this game help animals in distress by generating alternate thoughts to promote positive feelings and wholesome behavior.

Attention Deficit Hyperactivity Disorder (ADHD)

ADHD is a brain disorder characterized by continued distraction, unnecessary and frequent movement or talk which may be disruptive, and actions exhibiting impatience or lack of forethought. Drawn to Distraction (Goldman et al. 2014) is a game intended to convey to caregivers of children affected by ADHD and non-caregiving people that people with ADHD have a stronger drive to engage in activities offering immediate rewards even when they know that activities offering much higher rewards and requiring patience are available. The game is intended to convey that ADHD symptoms may be mistakenly perceived as intentional negligence. Such a misunderstanding can result in a punishment for a child not doing a homework instead of treatment for ADHD. The playing character in the game is expected to reach library to study for an upcoming examination which is an activity with higher and delayed reward, resisting the temptation to play a game called Space Raiders which represents an activity with low and immediate reward.

Autism Spectrum Disorder

Autism spectrum disorder is a developmental disorder that refers to problems in interaction with other people which vary in type and severity. Autistic people are often very shy which can lead to problems in relationships and professions requiring interaction with coworkers, peers, bosses, or customers. Pinwheel (Kolakowska et al. 2017) is a game playable on tablets which has been used to measure progress of children with autism spectrum disorder. A child has to

flip the tablet correctly to move the colored ball from the base of the pinwheel's stem to the petal with matching color. Sensing by touch screen, accelerometer, and gyroscope provides information in addition to the information recorded by the game. The number of successful and wrong hits and mean reaction time for them are among the six gameplay features used to measure progress in one or more areas of development. Fine motor skills and attention control are among the ten areas of development used in this study. Therapists' evaluations of 31 children in the 10 areas of development along with gameplay statistics were used as training data for supervised inductive machine learning. The goal of machine learning in this study was to learn to predict child development in different areas using gameplay statistics. Child development-related decisions found by the learning program can be used by therapists in their decision-making. This study is an excellent example of the synergy of qualitative decision-making by humans and intensive computation by computers.

Diabetes

Diabetes results from insufficient insulin or inefficient use of insulin. Uncontrolled diabetes leads to excessive glucose in blood which can damage vision, nerves, kidneys, and increase the risk for cardiovascular disease. Food Quiz (Glasemann et al. 2010) is a game which teaches diabetic people to count carbohydrate content in food, since carbohydrate intake affects blood sugar. A player is shown a plate with food and asked to find the number of bread units in the food. One bread unit represents 10–12 g of carbohydrates in Germany depending on the geographical region. Lower levels of this game show individual food items. Higher levels of the game show a combination of food items or dishes. Mario Brothers is an open-source game. Its modification presented in (Chen et al. 2011) is intended to educate diabetic children. Mario – the main character of the modified game, has type I diabetes. Mario has to control his blood sugar during his mission to save the princess locked in a castle. The player has to control Mario's blood sugar by making wise choices about food intake, exercise, and insulin injection. Power Defense (Bassilious et al. 2012) is a game intended to improve the ability to understand and control the numbers related to management of type I diabetes. In brief, food attacks a reactor-based base station which represents the diabetes patient in this game, and the player has to survive the attacks by ensuring that the amount of energy (represented by food) reaching the base station is in acceptable range. The reading of the power-output meter of the base station represents blood sugar.

Hygiene

Hygiene is about maintaining a clean body and environment to minimize the chance of spreading infectious diseases. MicrobeQuest! (Molnar and Kostkova 2015) is a game which allows the player to explore human hand or body or food to learn about microbes, microbe transmission, and food-and-body hygiene.

Maternal Health

Improper nutrition during pregnancy can lead to poor health outcomes for children. Ultrasound examinations during pregnancy help in assessing fetal health and growth. EasyCare (Font et al. 2017) is a game for educating women on nutrition and water consumption during pregnancy and after delivery and ultrasound examinations during pregnancy.

Nutrition

Child obesity is a serious problem since obesity increases risk for many chronic health conditions which lead to death or permanent disability. The comic-book-style interactive storytelling mobile application in (Amresh et al. 2015) educates children on healthy eating to prevent overweightness and obesity. The application is intended to teach children to create a balanced meal and incorporate

physical exercise in their schedules. A child can replay to select different choices to find a winning combination.

Physical Exercise

Physical exercise is very important for maintaining/improving strength, flexibility, and cardiovascular health and preventing or delaying the onset of many serious health conditions. Physical exercise also plays a very important role in improving/maintaining mental health. World of Workout (Bartley et al. 2013) is an application promoting physical fitness through physical exercise. A player can improve the speed, strength, and stamina of his avatar by doing relevant exercises. Activities that don't require a significant change in the player's location (push-ups, jumping jacks, and sit-ups) are recognized using accelerometer in his/her smartphone. Activities needing significant changes in the player's location (walking, running, and sprinting) are recognized by analyzing the information provided by the GPS (global positioning system) in the player's smartphone.

Physical Therapy

Physical therapy is intended to improve quality of life by improving posture, balance, mobility, flexibility, or strength. Candidates for physical therapy include but are not limited to athletes, developmentally challenged children, and stroke survivors. The computational intelligence-based architecture in (Afyouni et al. 2014) includes a route recommender which accepts primitive hand gestures recommended for a disabled patient by a therapist along with movement constraints (speed of movement, maximum range of motion, and number of repetitions of the movement) and generates a customized route in the gaming environment for the patient to move hand accordingly, to undergo physical therapy. iSpine presented in (Hsu et al. 2013) is an educational entertainment system for children suffering from scoliosis. People with scoliosis have an abnormally curved spine. Though most scoliosis patients have a mild form of it, severe scoliosis can cause damage to lungs and heart and increase the risk for chronic back pain. iSpine is designed to teach 9 orthopedist-designed physical exercises and 33 spinal health concepts. iSpine allows children to improve the health of their virtual pets by performing physical exercises. iSpine uses motion-sensing devices.

Sexually Transmitted Infection (STI) and Cervical Cancer

Human papillomaviruses (HPV) infect millions of people worldwide each year. HPV is the most common STI. High-risk HPV can cause different cancers including cervical cancer. The game in (Nirmal et al. 2013) is intended to educate people on HPV and cervical cancer. Up to four players can play this game at a time. A player earns a card by correctly answering if the given statement about HPV or cervical cancer is a fact or myth, but taking an educational test with these questions costs coins. The feedback from 111 participants showed that around 96% gained some or significant knowledge by playing the game. UnderControl (Guana et al. 2014) is a multilevel mobile game which educates players on available contraceptives, safe sex, birth control, and ways to prevent STI.

Conclusion

Though results obtained from computer games and game-like virtual environments developed for public health education are impressive, many of these games are not available in public domain. Also, there are still many major health conditions and their special cases that have not been addressed by computer games.

Definition

Puyo Puyo is a series of tile-matching, two-player, and real-time puzzle games published by Compile Inc. and Sega Inc.

Introduction

Puyo Puyo is a series of two-player real-time puzzle games published by Compile Inc. from 1991 and Sega Inc. from 2002. Over ten titles have been published for over ten platforms and have been played and studied for a long time especially in Japan.

Puyo Puyo is a kind of tile-matching puzzle game with dropping tiles such as Tetris, Dr. Mario, or Columns. While such games were mainly designed as one-player game, it is important that Puyo Puyo was designed as a two-player game, and many competitions have been held for expert players, like the cases of fighting games or real-time strategy games.

In this entry, core rules, brief gameplay, and some approaches from researchers are described, as detailed rules and characters of each title; history and anecdotage are omitted.

Core Rules

There are many rules in Puyo Puyo series, and different set of rules are used in each title or each game mode. Here the most common ones are described. As the official page (http://puyo.sega.jp/ is in Japanese, English Wikipedia (http://puyonexus.net/wiki/) may be useful.

Number of Players and Boards

Puyo Puyo is usually played by two players; each player has his own board (field) with about 6×13 tiles (Fig. 1a), as both boards are open to be looked at.

While a single board is shared by two players and they can interfere the other directly in chess, Go, or fighting games, players can interfere the other only indirectly through "chain" in Puyo Puyo.

Operations

In Tetris, the connected four tiles called tetromino are given to the player, the kind of tetromino is randomly selected from seven candidates, and the player rotates/moves horizontally and drops it. In Puyo Puyo, each tile is called puyo, and usually each puyo is colored. In each turn, connected two puyos are given; the player also rotates/moves horizontally and drops it (Fig. 1b). Colors of given puyos are randomly selected from four candidates, but the next four colors (of the next two turns) are announced (Fig. 1c).

In contrast to sequential games such as chess, actions and events of players in Puyo Puyo are

processed in a real-time manner, and almost no synchronization is done. Aside from the intended drop by a player, the given two puyos are drop gradually by time.

State Transition

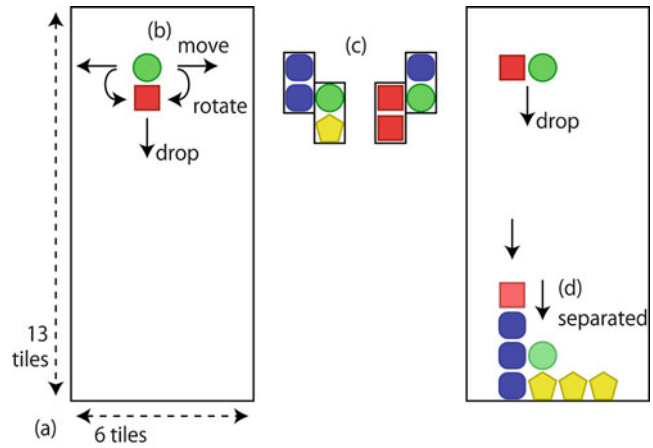
When one of the two given puyos grounds on the bottom edge, or one of the existing puyos, the player's operation is complete. In contrast to the case of Tetris or Dr. Mario, two puyos can separate and drop independently to the surface (Fig. 1d).

If four or more puyos of the same color are connected horizontally or vertically, they are eliminated from the board (Fig. 2a). After some puyos are eliminated, there may be some puyos over them. Such floating puyos fall to the surface (Fig. 2b). After the fall, if four or more puyos of the same color become newly connected, they are also eliminated (Fig. 2c). Such cascade of elimination is called a "2-chain." In the same way, 3-chain, 4-chain, or n-chain may occur.

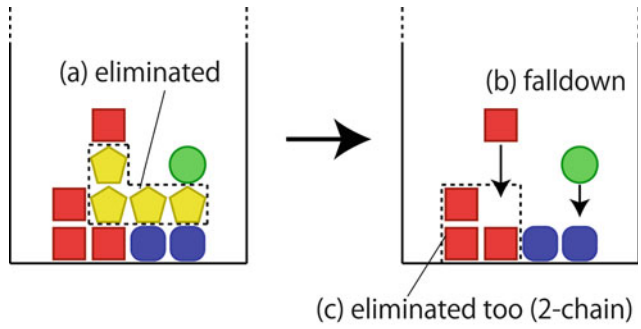
Attack and Win

Each player gains his score mainly by finishing a chain, though there are some other resources such as just dropping puyos or clearing all puyos. By gaining a score, the player can attack the opponent by sending "garbage puyos" (or "nuisance puyos"). The longer the chain or the more puyos eliminated, the more garbage puyos are sent.

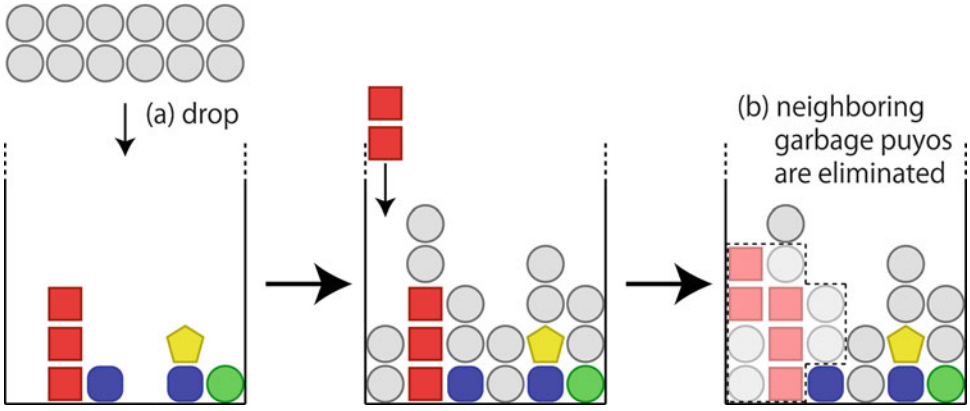
Sent garbage puyos are dropped to the surface after the operation of the attack player (Fig. 3a). Garbage puyos cannot be eliminated by themselves; then usually they disturb the making of chain of the attacked player. Garbage puyos can be eliminated only if neighboring colored puyos are eliminated (Fig. 3b).



Puyo Puyo, Fig. 1 Boards of Puyo Puyo and possible operations



Puyo Puyo, Fig. 2 Elimination and chain



Puyo Puyo, Fig. 3 Garbage puyos

An essential rule "cancelation" of garbage puyos was introduced at Puyo Puyo 2, and now the rule is used as a standard. When both players executed chains and sent garbage puyos, they can cancel and only the difference of the amounts is sent. For example, player A sends 140 garbage puyos by 7-chain, player B sends 60 garbage puyos by 5-chain, then only 80 puyos are dropped on the board of player B. When the third column from the left is filled, the player loses the game.

Game Modes

Several game modes are available in commercial titles of Puyo Puyo, and different skills are required.

1. Story mode, human versus computer. Human player plays against about ten enemies sequentially. Each enemy has its own character, such as skeleton or mage, and own strategy to play.
2. Human versus human. Usually rule set can be modified, and handicaps can be added.
3. Endless mode, human only. Only one board is used, the goal of this mode is not beating the opponent but gaining as much score as possible. The speed of unintended drop becomes faster gradually.
4. Quiz mode. Single board with preset puyos is given, player plays to realize the given goal such as "do 4-chain" or "clear all puyos" in some turns. Usually long time is given to think.

Gameplay and Basic Strategies

Though required skills for each game mode are a bit different, here "human versus human" is assumed and the basic strategies for it are shown. The main way for attacking in Puyo Puyo is to prepare and execute the chain, and the longer chain can attack more strongly. Between intermediate and expert players, it is required to prepare long chain such as 13-chain, as faster as possible, with less weak point to be exploited and with checking and disturbing the opponent preparation.

Preparing Chain

To construct and prepare chain is the necessary skill for Puyo Puyo. Here some basic shapes of chain preparation are introduced.

Figure 4a shows the basic shape called "stair 5-chain." By eliminating the leftmost blue puyos, yellow, red, green, and finally blue puyos are eliminated step by step. The amount of garbage puyos sent by this 5-chain is about 60, then almost enough to win if the opponent cannot cancel. In the Puyo Puyo 1, before the introduction of cancelation rule, the only point to win was to execute 5-chain before the opponent.

Figures 4b–d show other shapes of 5-chain, though the order of eliminated colors is the same. As there are a lot of and varied shapes in chain, each of them has its own advantages and disadvantages, an adequate one should be selected

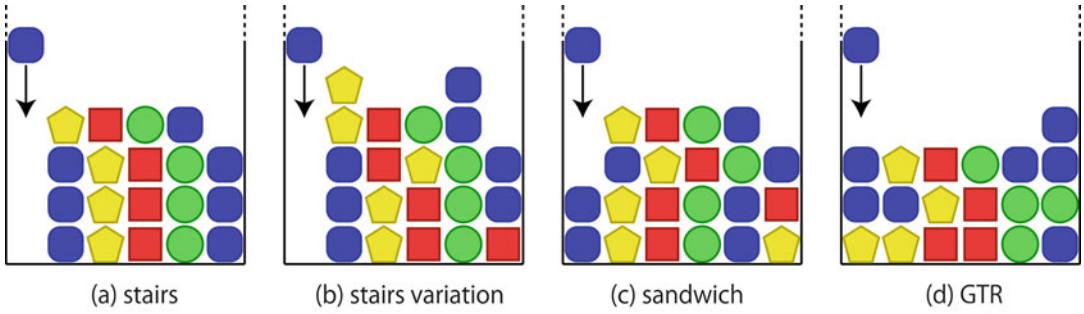
by considering the given puyos and the opponent situation.

Figure 5 shows an advanced but famous shape called "transition." By eliminating the rightmost upper yellow puyos, chain proceeds to left, and at the left edge the direction transits to right; finally 11-chain is executed. This 11-chain includes 5-chain shown in Fig. 4a, but usually this subpart is not constructed at first; the left side of 11-chain (transition part) is preferentially constructed at first. Sometimes, one more transition part is constructed at near the first yellow puyos; totally about 15-chain can be done.

Decreasing Time Loss

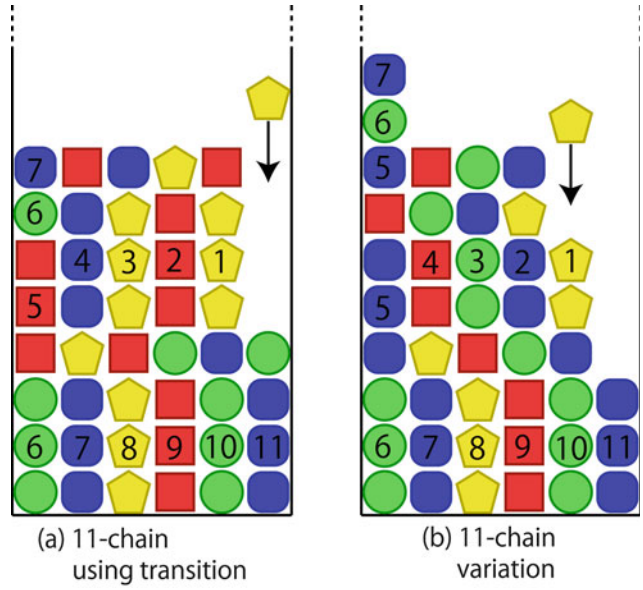
As Puyo Puyo is usually a real-time game, a time loss by operation delay causes the loss of number of dropped puyos, then the loss of possible chain length, and finally the loss of winning probability. There are some other factors to make a time loss:

– Elimination of puyos: Especially, beginners tend to eliminate four puyos which seem to be useless for chain, but this elimination sends almost no garbage puyos, decreases the resources, and produces a time loss equivalent to about one move. Longer chain also needs



Puyo Puyo, Fig. 4 Examples of 5-chain variations. (**a**) is the base called 3-1 stairs, (**b**) is the variation, (**c**) is called sandwich, and (**d**) is called GTR

Puyo Puyo, Fig. 5 Examples of 11-chain by transition



longer time; this is an important factor to be discussed in the next section.
- Drop of garbage puyos: One or two garbage puyos are not so disturbing the preparation of chain, but the dropping produces a time loss equivalent to about one move. Then it is valuable to cancel completely the opponent attack even in the case of smaller attack.
- Separation of puyos: When the operated puyos are separated (Fig. 1d), unignorable time loss is produced. Generally, fine ordered shape such as Fig. 4a requires more separations and then other shapes such as Fig. 4d can be selected to reduce the separations.

Timing of Attacks

Assuming the case that player A can execute 11-chain and player B can execute only 10-chain by some delay or unlucky, it is even not preferred for player A to execute 11-chain immediately. Finishing 11-chain requires a long time so that player B can drop over 20 puyos; so probably player B can counter by 12-chain or more. Except the case where a very long chain can be luckily constructed very effectively, the first attacker of long chain is disadvantaged.

For forcing the opponent to execute the long chain at first, it is a frequent tactic to prepare and execute "secondary gun" of about two- to 4-chain separately from main chain (primary gun). There are some possible reactions for the opponent against this fast and medium attack:

1. Nothing: When the preparation of long chain is too effective, often many puyos are required to start and counter against fast attack may be impossible. Then usually preparation with less weak point is needed, and also preventing the opponent from too effective preparation is needed by checking.
2. Receiving the attack: When the attack is smaller, such as plain 2-chain producing six garbage puyos, sometimes it is better to receive the attack as is. The receiver suffers six garbage puyos, but the attacker lost eight puyos as resources and some time to eliminate them.
3. Countering by the primary gun: Assuming the case the receiver has 11-chain as his primary gun, and the attacker executed 4-chain; probably the attacker's primary gun is about 7-chain, considering the amount of resources. It is not so easy to expand 7-chain to 11-chain or more by using the expected time for finishing 11-chain counter. So, the counter by the primary gun can be the best way in some situations.
4. Countering by small attack: When the counter by the primary gun seems to be not good, it is often done to counter by secondary gun or a part of primary gun. In addition, 4-chain against 2- or 3-chain can be a good counter to press the opponent to start the primary gun. "Secondary gun war" keeping primary guns is typical among expert players.

Such tactics for timing of attacks are based on the observation of the opponent board. Players are requested to play rapidly, to observe accurately, and to change the tactics depending on the situation.

Related Works

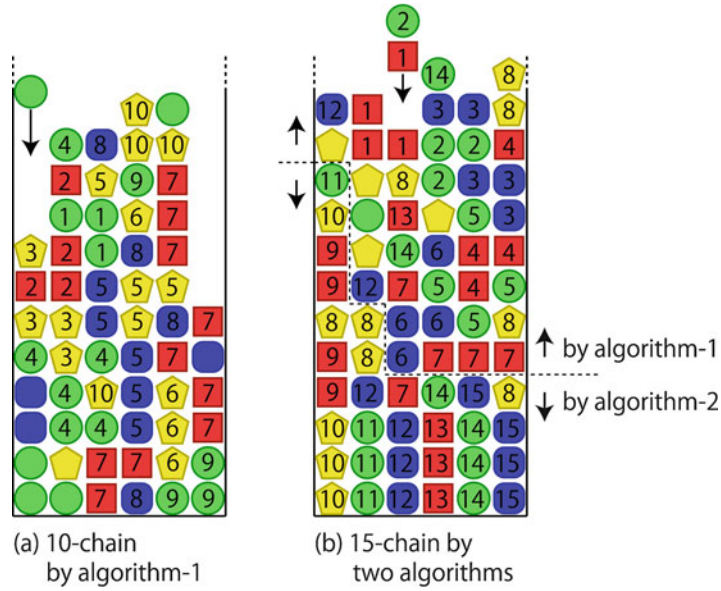
Main participators of Puyo Puyo may be publishers, players, magazines, shops, video game arcades, or competition organizers. But there are some approaches from different positions.

Analysis

As chain preparation is the core issue in Puyo Puyo, the complexity of it has been often discussed. For example, it was proven that the complexity to find the maximum chain length (when the colors of given puyos are known) is NP-complete (Matsukane and Takenaga 2005). Also the complexity to judge whether all puyos can be eliminated was proven to be NP-complete. Such facts are not important for real battles but attracted much attention as academic works on this very popular game.

Chain Construction Algorithm

According to the randomness of given colors and the complex elimination rules compared to Tetris or Dr. Mario, it is not easy to make an algorithm to



Puyo Puyo, Fig. 6 Chains generated by two algorithms

construct long chain. For a long time, computer players of official titles could execute only about 5-chain at max and they are not good rivals of intermediate or higher players.

At 2012, two algorithms for constructing long chain such as 11-chain were published (Ikeda 2012). The first algorithm extracts all possible future states after the next three moves and selects the move which can cause the biggest attack at depth 2 or depth 3 node. Figure 6a is an example of 10-chain by this algorithm. In order to improve the efficiency, second algorithm utilizes the "regular forms" developed and used by human, through tree search and matching evaluations. Figure 6b is an example of 15-chain by two algorithms.

Playable Clones

There are many official/unofficial clones for Puyo Puyo. By using them, many battles among humans via the Internet have been done, and many competitions among computer programs have been held like as the StarCraft case (see ▶ "StarCraft Bots and Competitions"). As there are many strong computer programs whose algorithms are nondisclosed, in such programs not only preparing chain but also tactics described in 3.3 seems to be well managed. For example, at 2012, a strong program "Niina" played against three strong human players and won 150 games in 217 games (http://sengiken.web.fc2.com/html/AI/vsAI201205.html (in Japanese)).

Quality Assurance-Artificial Intelligence

Kazuko Manabe
Square Enix Co., Ltd., Tokyo, Japan

Synonyms

Automated testing; Bug detection; Game balancing; Software testing

Definition

Quality assurance (QA) verifies that product performance and functions meet specifications. Quality assurance-artificial intelligence (QA-AI) refers to the method of AI used for QA or the program or service using that method.

Introduction

Digital games increase in complexity year after year. Additionally, the burden on QA of work such as error correction and game balance adjustment has also increased. There are various methods for QA; however, one of the most fundamental actions is playtesting games. Content adjustment and debugging work are both performed frequently from the early stage of development to the final stage. Although there is no doubt this is important work, games developed in recent years have increased in complexity making it difficult to achieve sufficient number of trials by humans alone. Therefore, research on automatic play using AI agents is becoming more popular year after year.

AutoPlay has long been the subject of research as a method of creating opponents and allies for humans. When using an exploration method, it is naturally necessary for an opponent in the game to have a certain degree of strength, but it is also necessary to make adjustments, such as restricting the opponent or ally's strength or ensuring that tactics are taught to the player. This is simpler for the agents used in QA since it is not necessary to consider such entertainment value. For example, in order to find a factor that breaks the balance of strength, it is necessary to create an agent that pursues only strength, without adjusting strength at that time. Accordingly, it is highly likely that agent creation methods for more sophisticated game contents can be applied

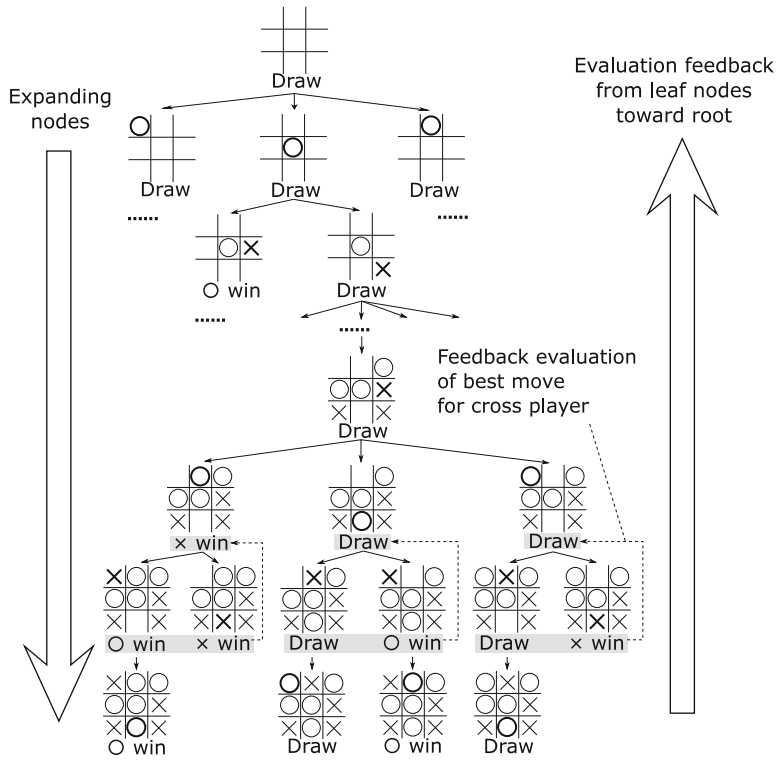
for creating QA agents. Best method for player agents changes depending on type of game, degree of freedom of player, goal that agents should reach, development environment, updating frequency, budget, and other factors.

In this section, we will cover various creation methods and actual examples of player agents that may be useful for QA, irrespective of their original purpose and focusing reasons of their adaptability. Game tree search and Monte Carlo tree search are effective for creating player agents for games with small state spaces. Character AI can create agents that are easily customizable in detail in exchange for flexibility for unknown environments. Genetic algorithm is well suited for searching for the best combination among a vast array of choices. Neural networks and Neuro Evolution of Augmenting Topologies are often used when the state space is large. Reinforcement learning is useful when one wants to focus on adaptation to an unknown environment. Reinforcement learning can be combined with NN and DNN to deal with larger state spaces.

Game Tree Search

A game tree is a non-cyclical, directional graph of state transitions representing game states as nodes and edges as actions for changing states. By searching a game tree, it is possible to arrive at the action that should be selected in the current state. For example, the game tree for *Tic-Tac-Toe* would be as shown in Fig. 1. Here, omissions are indicated by ellipsis. This tree is obtained by recursively repeating the process of expanding child nodes by the number of possible actions from the root node in the current state until there are no more nodes that can be expanded. However, if there are nodes that are effectively in the same state, the number of nodes to be expanded can be suppressed. In this figure, taking into account rotation and symmetry, the first player can only take one of three actions. In the case of *Tic-Tac-Toe*, when all the nodes are expanded, the terminal leaf node always results in a victory of one player or a tie resulting in an evaluation value. Each player can determine the evaluation value of the parent nodes based on the policy of selecting



Quality Assurance-Artificial Intelligence, Fig. 1 An example of an expanded game tree in tic-tac-toe

the best move for themselves; thus, the evaluation values can be given to all nodes toward the root node. Based on these evaluation values, the agent can select the next action.

In games such as *Tic-Tac-Toe* and *Othello*, it is possible to create a very strong agent by searching the game tree (Russell and Norvig 2009). Deep Blue, which beat the world champion at chess in 1997, also uses a game tree search (Campbell et al. 2001). Since Tic-Tac-Toe has a small board, it is not difficult to describe all states. However, for general games, node creation must be aborted part way through the process due to processor and memory constraints. For that reason, how accurately an agent can evaluate the state of an unfinished game determines its intelligence. For example, in *Othello*, there are distinctive features on the four corners and sides of the board, making it easy to evaluate properly even if the game state is not the end state. Therefore, it is easier to make a strong agent. On the other hand, *Go*, which belongs to the same category of board game, has a large board and only small differences of position unlike *Othello*. It does not have various pieces unlike *Chess*. It is difficult to make strong agents in such games that have many candidate moves and few strong features in their states for simple game tree search (Sei et al. 2005). Pruning such as by Alpha-Beta Search (Schwab 2004), which does not create unnecessary nodes for best move selection, is a method of improving the game tree search. In addition, in the event a sufficient number of states cannot be expressed after pruning, methods such as a Monte Carlo Tree Search exist whereby state is evaluated by cutting off node creation at a certain depth and conducting a simulation thereafter.

Monte Carlo Tree Search

The Monte Carlo method is a random sampling algorithm for estimating an amount that is difficult to strictly calculate. An approximate solution is obtained by generating many samples including random numbers. A Monte Carlo Tree Search (MCTS) is a search method that applies the Monte Carlo method to a game tree search (Coulom 2006). As described in the previous section, when a game tree cannot express all states, the strength of an agent is determined by how accurately it can evaluate the state of an unfinished game. MCTS is a method of estimating the evaluation value of an intermediate state using a large number of simulations including random numbers. After creating an appropriate number of nodes (generally a few to several dozen moves from the current state), the evaluation value of the state is obtained by following a certain policy to the leaf node and conducting a simulation after the leaf node (referred to as a rollout or playout). Although there are many variations for rollout policy, they all contain probabilistic calculations. In order to obtain a more accurate evaluation value, it is necessary to perform the rollout many times using more computing resources.

Although MCTS is primitively not suitable for problems that have many numbers of states, it is possible to apply to them by reducing the number of states in some way. For example, Ikehata and Ito created discrete states in *Ms. Pacman* (from Namco in 1981 (Ikehata and Ito (2011)), an action game in which the aim is to eat all the dots on the map while avoiding enemies, by dividing the map by the cross points of the route and using MCTS to create an agent (Ikehata et al. 2011). They searched more efficiently and obtained a score much higher than the world record at that time by switching the directive between "survival" and "eat" based on the results of the MCTS. Gosling and Andruszkiewicz used MCTS to select the appropriate strategy in the real-time simulation *Total War: Rome II* (from Creative Assembly in 2013 (Gosling and Andruszkiewicz, 2014)) and created a campaign AI. In doing so, they compiled an enormous number of actions into a meaningful task sequence and made it higher dimensional.

MCTS can generate all possible actions in arbitrary states and can be executed in just a simulation environment. Although it is a problem to need calculation resource, the constraint is not so strict for QA agents unlike the previous two examples that execute on runtime environment. Parallelization will be great help to accelerate it because simulations run independently. Also,

Q

since the search is performed in runtime, it has the benefit of being unaffected by game updates and other changes. On the other hand, it is difficult to debug and adjust hyperparameters. They are common problems with probabilistic methods.

Character AI

There are several widely known methods for making characters act as enemies or allies in a game. These include state-based agents, which are created by describing the state, actions taken in each state, state transition conditions, and goal-based agents. The behavior of goal-based agents is defined as a set of hierarchical goals (Buckland 2004). If agents can be created using such character AIs, it becomes possible to create a test agent that can be made to repeatedly take determined actions.

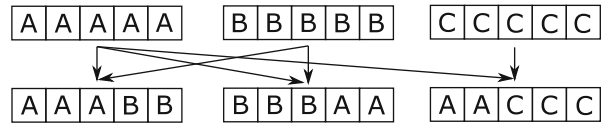
For the *Yakuza* series from Sega Games a test was conducted using a rule-based agent created by describing the preconditions and actions to take when the conditions are met. The system secured numerous calculation resources at a low cost and conducted builds and tests automatically using computers after the developers returned home. Having started with a simple test, such as a collision error check, it is now possible to perform more sophisticated error checking. It is possible to complete the game while switching modes depending on the game situation. Likewise, for *Horizon Zero Dawn* (from Guerrilla Games in 2017) an automatic test was conducted using agents that take simple actions. By running 24 h, 7 days a week test, a wide map of the open world was covered (Barbuta 2018).

Because many methods of Character AI were originally developed as game content, they have historically commonly constructed in a deep part of the game-system architecture. It needs re-implementation according to specification updates and it is difficult to use the same code for other games. However, it does not need much time to implement an executable first version. In addition, it is possible to customize even small behaviors. These features indicate that Character AI is a suitable method in the middle of development phase where its specifications can change daily. Doing many unit tests that rely on the game content is also a good practice for Character AI.

Genetic Algorithm

A genetic algorithm (GA) is a technique that mimics the evolution of living organisms and is used for combinatorial optimization problems. Learning is carried out by having solution candidates compete (Luger 2002). Solution candidates are called individuals and are represented by gene sequences. One gene represents one parameter. After randomly generating a plurality of gene sequences, the GA cuts the sequences at one or more randomly determined points and reconnects them. The evaluation value for the problem, or "fitness value," determines whether an individual is used for this crossover processing. In this way, only excellent genes pass on to the next generation and the sequence is gradually improved. Figure 2 is an example of a crossover where the good fitness values were in A, B, C order. The better the fitness value of the individual, the higher the possibility that many genes will be passed on.

In *Astronoka* (muumuu 1998), enemy characters evolve by GA. Players set traps and the characters that clear them to remain and proliferate (Morikawa 1999). Therefore, players must always think about new traps. The genes express the enemy properties and action patterns, so game designers do not have to adjust their parameters. In addition, the number of generation is adjusted dynamically to keep the improvement of the fitness value at a constant speed. GA meets the *Astronoka* game design specification that requires



Quality Assurance-Artificial Intelligence, Fig. 2 An example of Crossover

created agents to behave in response to the players' actions.

In *City Conquest* (from Intelligence Engine Design Systems in 2012), a two-player tower defense game, a stronger command than expected is discovered and the game balance is adjusted by performing a GA search of a "script" (sequence of commands) issued by the players (Champandard 2012). In this game, when the health points of one of the two players become zero, that player is defeated and the battle ends. Since the number of remaining health points of the winning player can indicate whether the battle was close, the health points are added to the fitness of the "script" of the winning player and subtracted from the script of the defeated player.

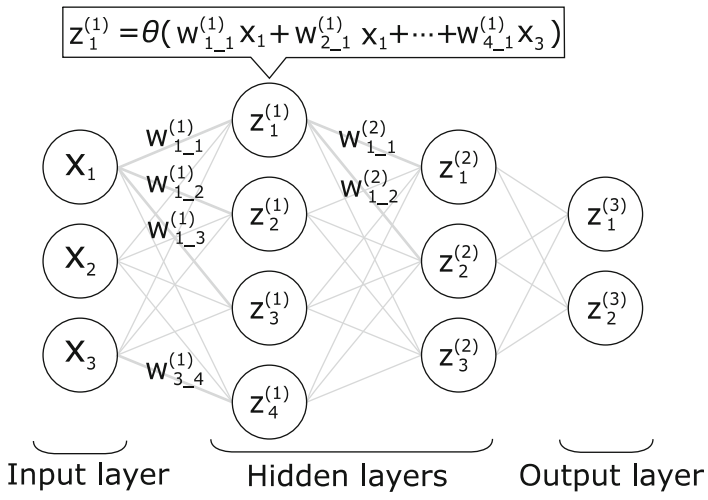
Grimms Notes Repage (from Square Enix in 2018) is a role-playing game that adopts an action battle that advances automatically. For the adjustment of the game balance, a search is performed by Genetic Programming, an expanded method from GA, to find strong party formations. Through this, pieces of equipment or characters which are overpowered can be found. For the gene structure, they used tree structure according to the party formation unlike GA that uses array structure. The difference between the remaining health points of the two players and the battle time are used for the fitness value (Manabe and Awaji 2018).

When searching in a space with many possible combinations, GA can be an option to search efficiently as long as it is possible to represent the candidates of the solution as genes. Similarly to the MCTS, it needs an exact and fast simulation environment. Also, the validity of parallelization and performance constraint is not strict if the method runs outside of the game.

Neural Networks

The human brain consists of many neurons. A network constructed by connecting neurons to each other is called a Neural Network (NN). A mathematical NN (sometimes referred to as an artificial NN as opposed to a natural NN, but we call it just NN in this section) modeled this way operates as a function that generates a unique output for a specific input. The layers between the input layer and the output layer are called the hidden layers, as shown in Fig. 3. A neural network with many layers is called a Deep Neural Network (DNN). There are DNNs often having a convolutional structure and an autoencoder algorithm. Learning that occurs using DNN is referred to as deep learning (DL).

There are not many applications in digital games of a neural network alone. In *Creatures* (from Millennium Interactive Ltd. in 1996), for which the oldest literature on the subject can be found, the intelligence of characters trained by players is formed by a neural network. Aggregates



Quality Assurance-Artificial Intelligence, Fig. 3 An example of a three layer fully connected neural network

Q

of neurons are called "lobes" and the neurons of respective lobes are connected (Grand et al. 1996). In addition, in *Black & White* (from Lionhead Studios in 2001), players can also raise creatures. A simple perceptron is implemented for the creature and the player can teach behavior by stroking or scolding it (Evans 2002). In the real-time strategy game *Supreme Commander 2* (from Gas Powered Games in 2012), the reaction when a platoon encounters an enemy unit is controlled using two-layer NN (Robbins 2013). As the input values, they used the number of enemy and ally units, life points, overall damage per seconds (DPS), moving speed, defensive strength, and other values which are expressed by numbers from 0.0 to 1.0. The action evaluation was calculated depending on whether their life points, DPS, etc. were improved or not after the actions. They used different NNs for four types of platoons in the game: land, naval, bomber, and fighter. In the result, each NN acquired personality. The training took about 1 h for each NN with 34 input nodes, 15 output nodes, and 98 hidden nodes. NN can be a solution to create a simple agent that reacts against inputs in a problem that allows only short training time.

Neuro-evolution of Augmenting Topologies

Neuro-evolution of Augmenting Topologies (NEAT) is an evolutionary technique that uses genetic algorithms to determine the weight and structure of connections (Stanley and Miikkulainen 2002). In *Final Fantasy Record Keeper* (from Square Enix and DeNA in 2014), NEAT was used to create a test agent for battle. The behavior of the agent in a battle is determined using a NN. As a result of learning, an agent was created that closely resembles a human being and takes a significantly tactical approach to the battle (Tomobe and Handa 2016). Adjustment of hyper-parameters of NN needs skill and it generally requires considerable time. Automated adjustment such as NEAT helps save time. However, it needs initial cost to create the structures and more computing resources to run simulations instead. Automated adjustment would work efficiently for rather large NNs.

Reinforcement Learning

Reinforcement Learning (RL) is a generic term for learning methods that carry out learning autonomously based on experience. The most common form of RL has three components: a search strategy that tests various actions, a reinforcement function that feeds back based on the rewards of the action, and a learning rule that connects the two. Historically, Microsoft Research investigated reinforcement learning of characters using their own fighting games (Graepel et al. 2004).

Shin Megami Tensei Liberation Dx2 (Sega Games 2018) supported map creation using Q-learning, one form of reinforcement learning (Matuda 2018). In the game, points are necessary to walk the map depending on the number of steps; therefore, the number of steps required for a map search must be estimated. Accordingly, the number of steps necessary for an assault was measured by making an agent, created using Q learning, walk the map with conditions added, such as passing a treasure box.

RL can search unknown environment autonomously using a reward policy against the environment. In some cases where the number of steps before a reward is too large, or there are too many branches, RL cannot search well. It needs some improvements, for example, giving a milestone reward, shorten the number of steps to get a reward, abstracting common sequence of actions into behaviors, or dividing large maps into smaller area explored only once.

Neural Network and Reinforcement Learning

In the card game *Race for the Galaxy* (from Temple Gates Games in 2017), an in-game battle agent was created by combining RL and NN (Duringer 2018). Two types of NN were separately prepared, one for evaluating the board and one for predicting the behavior of the opponent. These were

further divided into those for each expansion pack and instances where the number of battlers is "two" or "three and more." Several dozen NNs were trained in total. All inputs to those NNs were the same and board information such as deck information and whether special cards are included in the hand was used. An RL mechanism which backpropagates given rewards in the end of the games was used for the NNs and learning was carried out by self-play.

Unlike simple NN, RL is capable of learning long-term strategies by using longer state transition for learning. On the other hand, as mentioned in an earlier section, it needs some improvements if the number of steps to get a reward is too large. The learning time tends to be longer than simple NN. Therefore, RL would be cut out for games in which the update intervals are long.

Deep Reinforcement Learning

A combination of DNN and RL is called Deep Reinforcement Learning (DRL). In particular, a method using Q-Learning as a reinforcement learning method is called a Deep Q-Network (DQN). In DQN, the action value function of Q-Learning is replaced by a deep neural network.

DeepMind, which developed DQN, used a DQN in 49 2D *Atari* 2600 games and created an agent with only images as an input (Mnih et al. 2015). As a result, the agent outperformed conventional machine learning methods in 43 games and exhibited performance better than a human in 29 games. In addition to 10^120 deck compositions, *Othellonia* (from DeNA in 2016), which is a game that combines *Othello* and a card game, is a very complicated game in which the opponent's hand is invisible and combines elements such as strong randomness in the hand dealt. To manage this complexity, DeNA created a test agent using a DQN (Okumura 2018). In this scenario, the input is the board condition and the hand. That information is compressed using feature learning in order to input the status of the cards held, for which there are over 2000 kinds. Typically, the cards are expressed by one-hot vector, which has a single activated bit whose location shows its card type and inactivated bits fill the others. It means that the length of the vector must be 2000 if the game has 2000 types of cards. In addition, the length increases when a new card type is added. Feature learning in the game makes it possible to express all the cards with short vector of size 5. The data compression promotes the speed of the DQN learning. This agent showed an average win rate of 90% against the existing rule-based agent for the same deck.

In a NN, connection weights are often adjusted based on training data, but in reality, there may be no training data and we may want to create an agent for an environment that is unknown in the first place. Since a DQN automatically adjusts weights by self-simulation, it is useful for learning in such cases. However, setting the value function to an NN often does not work well. The true performance of DQN can be deduced by adding the following strategies. Experience replay selects past experiences randomly to use for learning and use them not only once but many times. Freezing the target network stabilizes learning by fixing the old NN at the target value of TD error. Reward clipping can be applied to various problems, without adjusting hyperparameters, by unifying the scale of reward to a fixed interval such as $[-1, 1]$. Skipping frames accelerates learning by carrying out learning every four frames.

Conclusion and Discussion

We introduced various methods to create QA agents as a representative of QA-AI for digital games. Although it is not limited to QA, AI for games has strict constraints in terms of development budget, man-hours, and time. Also, the specifications and the data of the games change frequently. For the latter reason, in digital games area, it is difficult to use methods that utilize big data such as supervised learning and data analysis, which show great performance in some other areas, because even if the data for the agents are collected, they become obsolete in a short time. Currently, full-scratched AI and autonomous learning or search based on reward policy are

major methods for game AI. For these methods, the higher the expression ability of the problems is, the longer learning/search time and the more difficult the control will be. It is important to select an appropriate method according to actual game development issues.

Query-by-Gaming

Ramazan S. Aygun and Vineetha Bettaiah
Computer Science Department, University of Alabama in Huntsville, Huntsville, AL, USA

Synonyms

Gaming controller; Spatio-temporal linear logic; Spatio-temporal querying

Definition

Building interfaces for a spatio-temporal query is challenging since a spatio-temporal query may require positions of specific objects in a series of

temporal instants while constructing the query. This chapter presents how gaming controllers could be used for creating spatio-temporal queries as a user plays a game. The querying engine retrieves relevant video clip segments from the database as the user controls objects by giving commands using the gaming controller. In the backend, the search engine analyzes video clips that satisfy the user's query based on the spatio-temporal logic. A sample application of query-by-gaming for tennis video games is also provided in this chapter.

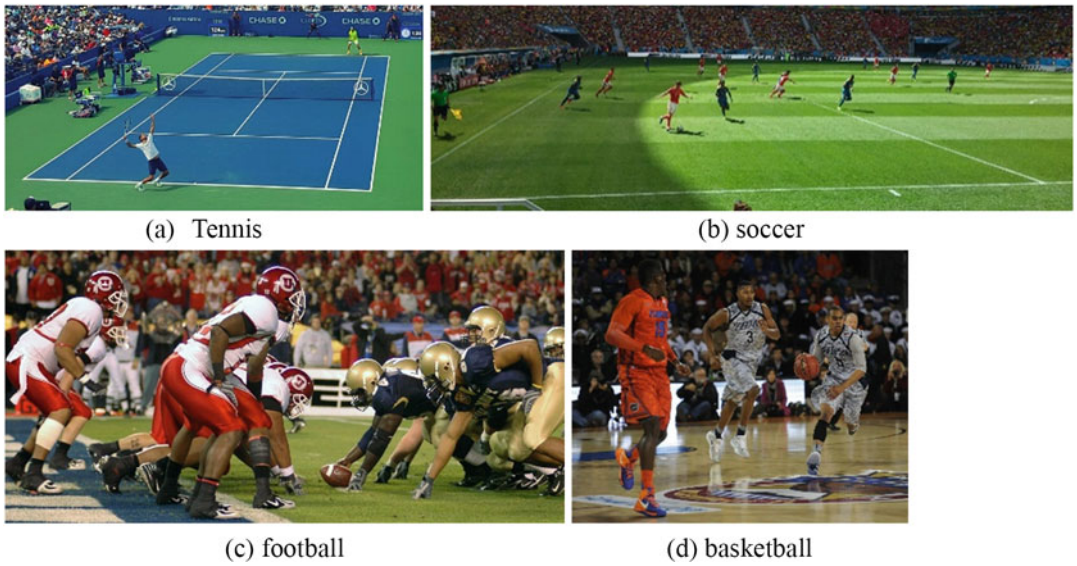
Introduction

Bridging the gap between users and database management systems require effective user interfaces. The main challenge of bridging this gap is to prepare interfaces that require minimal information to be learned about the system that executes queries. For complex querying systems beyond basic keyword search, menu-based interfaces have been popular for querying traditional relational database systems. However, building spatio-temporal queries is more complicated since these queries may involve associating locations to objects and changing positions of objects may need to be specified over a temporal interval or a series of temporal events.

A spatio-temporal query as the name implies has spatial and temporal components. For example, for a soccer video database, the query for retrieving "goals scored by Messi against Real Madrid *in the last 10 min outside the box*" has both spatial and temporal components. This query has a temporal constraint as "in the last 10 min" and a spatial constraint "outside the box." Despite being a spatio-temporal query, it does not have continuity of events. In other words, this query only checks an event that happens almost instantaneously. In this chapter, rather than focusing events instantaneously, the construction of queries that have a sequence of events is analyzed. For example, consider the query for retrieving video clips where "(i) in the mid-field, Messi passes the ball to Neymar, (ii) Neymar passes the ball to Suarez, (iii) Suarez passes the ball to Messi, and iv) Messi scores outside the box to the top left corner." To build this query, a simple, interactive, and incremental user interface would be necessary.

In this chapter, the methodology of "query-by-gaming" is explained as a way of getting input from users for constructing spatio-temporal queries. When various user interfaces for inputting data (e.g., keyboard, mouse, gaming controller, voice) is considered, it has been observed that gamers provide spatio-temporal information to the gaming engine in many game genres. Gamers control objects, move them, and generate actions based using gaming controllers. Moreover, considering the usage of technology, gaming has been popular environment not only for kids but also for old people. This observation is a motivation to use gaming controllers for spatio-temporal querying. Especially, for sports games such as tennis, soccer, football, basketball (Fig. 1), spatio-temporal querying could be achieved using gaming controllers.

Building interfaces for a spatio-temporal query is challenging since a spatio-temporal query may require positions of specific objects in a series of temporal instants while constructing the query. Having simple interfaces for spatio-temporal queries is desirable. This requires (i) developing a natural user interface, (ii) building query effectively in a simple way, (iii) integrating user into the querying and retrieval system, and (iv) getting user input in a seamless way. This chapter presents (i) building a natural interface by using the original video clips, (ii) using semantic sequence state graph as an indexing structure for query processing, (iii) integrating the user into the querying process by letting user play a game, and (iv) using a gaming controller for getting inputs from the user. This chapter is organized as follows. The following section briefly provides the state of the art work. Then the basic blocks of the querying system and utilization of gaming controllers for query-by-gaming are explained. Later the spatio-temporal query representation and execution are expressed. The last section provides the conclusion and discussion.



Query-by-Gaming, Fig. 1 Different sports where spatio-temporal querying could by applied. (Images obtained from pixabay.com)

State-of-the-Art Work

In terms of spatio-temporal querying, advancements have been made for developing languages to support spatio-temporal queries and enhancing interfaces for those queries. Spatio-Temporal Query Language (STQL) (Erwig and Schneider 2002) supports around 2,198 predicates about two evolving regions by extending SQL. Moving GeoPQL (D'Ulizia et al. 2012) extends Geographical Pictorial Query language and enables construction of queries by providing spatial properties of objects at different temporal layers. The temporal SOLAP (GIS + online analytical system) (Bisceglia et al. 2012) uses a temporal language named TPiet-QL in textual format. SQL-like SRQ (spatial relation query) (Della Penna et al. 2013) allows users to arrange visual objects (without temporal information). In visual graph-based query interface (Lu et al. 2014), four rectangular boxes are used to represent variables, conditions, video attributes and scenes while allowing two connections to attach to variable boxes or scene boxes. However, defining spatio-temporal queries with their interface is not an easy task for users.

Integrating time and handling temporal queries is challenging. While visual time automaton (Certo et al. 2013) supports time queries at different granularities, it requires users to know basic automata. On the other hand, multi-DST (dynamic spatio-temporal) querying system (d'Acierno et al. 2012) helps users build spatio-temporal queries by selecting multiple regions for an object with temporal intervals.

An alternative way of constructing queries is to use existing examples from the database. The query engine may build the query based on user browsing behavior (Yadav and Aygün 2009) or find similar videos to the browsed ones. The querying method using examples are usually named as "query-by-" followed by the type of the example used for querying. Pictorial Query-by-Example (Papadias and Sellis 1995), Query-by-Image Content (QBIC) (Flickner et al. 1995), Query-by-Humming (Ghias et al. 1995) (for music retrieval), and Query-By-Trace (QBT) (Erwig and Schneider 2000) are sample querying schemes of querying-by-example.

In quantizable video databases, the video could be represented a set of video instants such that missing parts could be predicted from these

instants (Jain and Aygun 2009). If the objects in a video visit the same locations, or in other words, if the spatial domain is restricted, these video databases are called recurrent databases (Naik et al. 2012). Query-by-gaming method is applicable to quantizable recurrent databases.

For efficient querying, the representation of spatio-temporal content in the database is important. Previously, a tennis video a clip was represented as a grammar-based string composed of objects, locations, and actions between them (Jain and Aygun 2008). Once a clip is represented as a string, the SQL's pattern matching could be applied for finding relevant clips. The queries are categorized into event-object-location, event-object, event-location, object-location, current-next event, projection, and semantic events. Using a menu-based system, the corresponding SQL patterns were generated. Since this system did not have an index structure, all strings had to be evaluated for pattern matching. Naik et al. (2008, 2012) proposed the semantic sequence state graph (S^3G) where states represent sets of object-location pairs and transitions between states represent semantic events. S^3G is a graph-based index where a user could start at any state (node) and traverse the graph to check if a sequence of events occurs or not. Moreover, S^3G allows to check whether a state is reachable from one state to another or not. Naik et al. (2008) used mouse interface where many windows pop up and the user had to choose the relevant positions of objects. Bettaiah and Aygun (2011, 2015) analyzed whether gaming controller could be more useful than inputting data through mouse clicks. Moreover, S^3G was improved by including the ranks of video segments in a video clip.

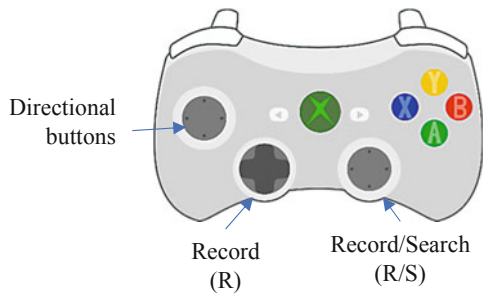
Overview of the Querying System

The querying system has two components: user interface and query processing engine. The key role of the interface is to help the user play the game with minimum intervention. As the user provides positions of objects using a gaming controller, the querying engine searches clips that are relevant to the user's query and displays the clip segment. In case multiple clips satisfy the user's query, the clip segment which appears in the same video clip as the previously displayed clip segment is given a higher priority for displaying next.

As the user provides positions of objects sequentially, the querying engine searches for clips in the system for every user query. Normally, conjunction is applied for each state provided by the user to determine video clips that satisfy all conditions provided by the user. In other words, only video clips that satisfy *all* states in the order user provides are retrieved. Hence, the number of clips that satisfy a user's query may decrease as the user increases the number of states to be satisfied thus making a stricter query. If the query becomes very strict, the system may not return any clip that would satisfy all states provided by the user. To hint about similar clips relevant to the user's query, the system also provides videos that partially satisfy the query by applying disjunction of video clips while executing the query.

Using the Gaming Controller for Querying

The user has to provide the locations of objects on the field. After selecting an object and using directional buttons on the controller, the user may assign positions to objects. Three types of button assignments are needed on the gaming controller (Fig. 2): (i) directional buttons for locating objects, (ii) recording positions of objects as a part of the query, and (iii) recording the position of the last object and then initiating search



Query-by-Gaming, Fig. 2 Assignment of buttons for querying

process. The system provides objects in an order and then the user needs to choose their locations using directional buttons. To complete the assignment of position to an object, the user presses the "record" button. The system provides the next object and so on. When the locations of all objects are determined, the user presses "the record/search" button. The major difference between "record" and "record/search" button is that "record" button does not initiate the search whereas "record/search" button informs the system that query at that instant is complete and then the system may start searching for states or video clips having objects at the corresponding locations.

Spatio-Temporal Query Representation

Let O be the set of n objects and $O = \{O_1, O_2, \ldots, O_n\}$. Similarly, let L be the set of m locations that objects could appear and $L = \{L_1, L_2, \ldots, L_m\}$. A state S is formed by a set of object-location pairs and $S = \{S_1, S_2, \ldots, S_p\}$. Whenever an object changes its position, a transition to a new state occurs. A video clip is represented as a graph of states. For example, the video clip in Fig. 3 has five consecutive states starting at state at S_1 and ending in S_5.

The states could be labeled as an initial state based on the initial positions of objects and as a final state based on the outcome. The transitions could be labeled based on the actions that cause state transitions.

Given a state graph in this form, the linear temporal logic (Vardi 2001) could be used to analyze a graph of vertices where each vertex represents a point in time. Since in this case, each temporal instant represents spatial information about objects, the spatio-temporal logic (Bimbo et al. 1995) is adapted. A spatio-temporal query can be expressed with negation (¬), disjunction (∨), conjunction (∧), implication (→), global (□), next (○), eventually (◊), until (U), and releases (R) operators as follows:

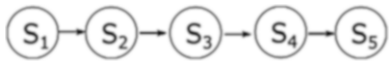
$$\Phi: = \theta \mid \neg\theta \mid \theta_1 \vee \theta_2 \mid \theta_1 \wedge \theta_2 \mid \theta_1 \rightarrow \theta_2 \mid \Box\theta \mid \bigcirc\theta \mid \Diamond\theta \mid \theta_1 U\, \theta_2 \mid \theta_1 R\, \theta_2$$

where θ, θ_1, and θ_2 are conditions evaluated at states. Negation, conjunction, disjunction, and implication operators are checked at a single state. Temporal operators (global, next, eventually, until, releases) evaluates whether a path satisfying the condition exists or not.

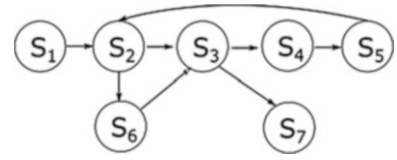
In this querying system, the most important temporal operators are the "next" and "eventually" operators. The "next" operator checks whether a specific state S_i is directly reachable from a current state S_c. The queries based on the *next* operator are named as subsequent queries. The "eventually" operator checks whether a specific state S_i is reachable from a current state S_c; however, S_i may not be *directly* reachable from the current state S_c. Such queries are named as eventual queries. Consider the state graph in Fig. 3 and assume that S_2 is the current state. For this graph, $\bigcirc\ S_3$ is true, but $\bigcirc\ S_5$ is false since S_5 is not directly reachable from state S_2. However, $\Diamond\ S_5$ is true since there is a path from S_2 to S_5.

The same state may be revisited in a video clip, and this may generate cycles of states in a video clip. For example, assume that the sequence of states is S_1, S_2, S_3, S_4, S_5, S_2, S_6, S_3, S_7 for a video clip and the graph for this clip is depicted in Fig. 4.

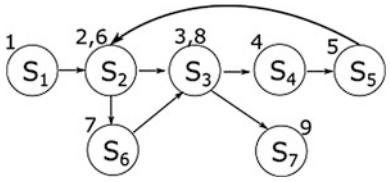
The graph in Fig. 4 returns true for the sequence of states S_2, S_6, S_3, S_7. This graph has also the sequence of S_2, S_6, S_3, S_4, although the video clip did not have these states in this order. In the video clip, S_4 is reachable from S_3 if the previous state for S_3 is S_2. If the previous state for S_3 is S_6, S_4 is not reachable from S_3 in the



Query-by-Gaming, Fig. 3 States of a clip



Query-by-Gaming, Fig. 4 Cycle of states for video a clip

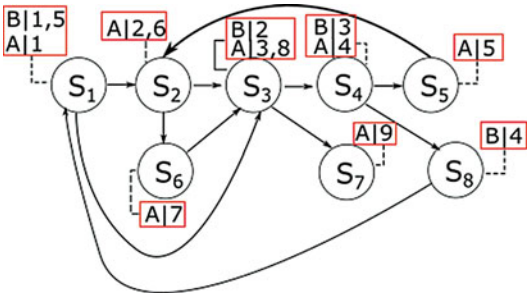


Query-by-Gaming, Fig. 5 Ranks of states in a video clip

video clip. This case shows that the ranks of states in a clip need to be maintained as shown in Fig. 5. States S_2 and S_3 have multiple ranks as they appear twice in the video clip. State S_2 appears as the second and sixth states whereas S_3 appears as the third and eighth states.

In a video database, there could be many clips that may share the same states. For example, assume that another video clip has the following states: S_1, S_3, S_4, S_8, S_1. If multiple clips are merged, the state graph loses specific information related to video clips. Thus, the ranks of states per clip are maintained. For example, if this clip is labeled as B and the previous clip is labeled as A, the state graph becomes as shown in Fig. 6.

This state graph representation can help to develop indexing for spatio-temporal querying. Semantic sequence state graph (S^3G) (Naik et al. 2008, 2012) is defined similar to a finite automata in the form of $M = [\mathbf{S},\mathbf{\Sigma},\delta,s_0,\mathbf{F}]$, where $\mathbf{S}$ is a set of internal states, $\mathbf{\Sigma}$ is a finite input alphabet set, s_0 is the initial state, $\mathbf{F}$ is a set of external states, and δ is a transition function mapping $\mathbf{S} \times \mathbf{\Sigma}$ to $\mathbf{S} \cup \mathbf{F}$. Each internal state is a set of object-location pairs. Let Σ_O and Σ_L be the set of objects and locations. Then, each object-location (OL) pair in a state S should be a subset a member of the cross product of objects and locations $OL \in \Sigma_O \times \Sigma_L$. The set of external states is optional but could be helpful when a series of states has an outcome (e.g., a player wins the points). The structure of an external state is the same as internal states. The transitions are represented with the alphabet ($\mathbf{\Sigma}$) and events caused by objects lead to transitions. In addition, each state has a set of clips. Each state also keeps the rank of each in a video clip.



Query-by-Gaming, Fig. 6 Representation of multiple clips in a state graph

Querying

Query-by-gaming has been evaluated on a tennis video database. In a tennis game, there are three objects: the ball and two players (player $_1$ and player $_2$). A state is composed of these three objects and their locations. The tennis court is divided into 13 locations based on the rules of a game (e.g., the areas where the ball must hit after a serve) (Bettaiah and Aygun 2015). Let L_b, L_1, and L_2 represent the locations of the ball, player$_1$, and player$_2$, respectively. If player$_1$ serves, player$_2$ becomes the next player and vice versa. Algorithm 1 provides the pseudo-code for the subsequent query. In Algorithm 1, Ω_C is the current state and Ω_N is the next state selected by the user. $C_{C,N}$ returns the set of clips that have both these states. $\overline{C_{C,N}}$ returns the clips where these states appear back to back using the ranks of states. Two lists are maintained as the user continues to build the query. One list ($\mathbb{Q}$) takes the intersection of all $\overline{C_{C,N}}$ to detect clips that satisfy the user's query. Moreover, the union of clips that satisfy the query at a point ($\mathfrak{V}$) are also kept.

The eventual query checks whether a state is reachable from a current state. Algorithm 2 provides the pseudo-code for eventual query. In Algorithm 2, Ω_0 is the initial state and Ω_F is the final state selected by the user for the eventual query. The algorithm first identifies whether there is a path from Ω_0 to Ω_F. For every path from Ω_0 to Ω_F, the intermedia states are determined. For each consecutive state, the clips that have both states are determined and then the ranks are checked if those states appear back to back as

```
void Subsequent_Query ( )
begin
  // L_b, L_1, L_2 represents location of ball, player_1, player_2 respectively.
  L_b ← Initial_ball_loc
  L_1 ← Initial_player_1_loc
  L_2 ← Initial_player_2_loc
  player_1_serve ← 1        // player1 serving
  player_2_serve ← 0
  ℧ ← ϕ   // List of clips having subset of the events queried
  ℚ ← ϕ   // List of clips having all the events queried
  // Play and pause the video at the first serve
  Ω_0 ← (L_b, L_1, L_2) // Initial State
  Ω_C ← Ω_0   // initializing the current state
  do          // setting the next state
    L_b ← Next_ball_loc
    if (player_1_serve = = 1)
      L_2 ← Next_ player_2_loc
      Ω_N ← (L_b, L_1, L_2)
    endif
    if (player_2_serve = = 1)
      L_1 ← Next_player_1_loc
      Ω_N ← (L_b, L_1, L_2)
    endif
    C_C,N = C_C ∩ C_N= Search (Ω_C, Ω_N) // search in S^3G for transition from Ω_C to Ω_N.
    C_C,N (overline) = ClipsWithOrder (C_C,N)
    ℧ ← ℧ ∪ C_C,N (overline)
    ℚ ← ℚ ∩ C_C,N (overline)   (in the initial run ℚ ← C_C,N (overline) )
    // Play the event from one of the clips in common clips from
    StartTime to EndTime
    // Pause the video at EndTime.
    // Switch the serve
    Ω_C ← Ω_N
  until ℚ = = empty OR no gamepad input
end
```

Query-by-Gaming, Algorithm 1 Subsequent query for query-by-gaming

in the subsequent query. Fig. 7 shows the interface for tennis video database application.

Conclusion and Discussion

Query-by-gaming can effectively be used for building spatio-temporal queries and then these queries can be executed using the semantic sequence state graph (S^3G). While the user plays a game, the querying system analyzes user inputs on controlling objects and then displays the video segment that is closest to what the user has provided for the continuity of the game. The search engine processes all user states and eventually presents the actual result of the user query. Moreover, the search engine also keeps the clips that satisfy the partial user query as the

```
void Eventual_Query ( )
begin
// Ω0(Lb, L1, L2) represents location of ball, player1, player2 respectively, in the initial state Ω0
// ΩF(Lb, L1, L2) represents location of ball, player1, player2 respectively, in the final state ΩF
   // Ωa…b represents the set of intermediate states between Ωa & Ωb
   // Ωa…b[i] represents the ith intermediate state between Ωa & Ωb
   // Cp represents clips in state Ωp ;

   // set initial and final states
    Ω0(Lb, L1, L2) ← (Initial_ball_loc, Initial_player1_loc, Initial_player2_loc)
    ΩF(Lb, L1, L2) ← (Final_ball_loc, Final_player1_loc, Final_player2_loc)

    ℧ ← Ø  // List of clips having subset of the intermediate events between Ω0 & ΩF
    ℚ ← Ø   // List of clips having all the events between Ω0 & ΩF
    Initial_Present = SearchState (Ω0) // check presence of initial and final states
    Final_Present = SearchState (ΩF)
    if  not (Initial_Present)  OR  not (Final_Present)  then
          Print "Queried state/states does not exist"
    else
      Ω0…F = SelectConnectedStates(Ω0,ΩF)       // Ω0,F – Intermediate States
      if  Ω0…F = = Ø
          Print "Cannot reach the FinalState from InitialState"
      else
        for i in range( 0 to | Ω0…F|-1) : // check the ranks of clips
          Ωp= Ω0…F[i]
          Ωq= Ω0…F[i+1]
          Cp,q = Cp ∩ Cq
          C̄p,q = ClipsWithOrder (Cp,q)
          ℧ ← ℧ U C̄p,q
          if (i==0) then ℚ ← C̄p,q   else ℚ ← ℚ ∩ C̄p,q endif
        end
   end
```

Query-by-Gaming, Algorithm 2 Eventual query for query-by-gaming

query is built. S^{3}G has a low complexity for executing the subsequent query (O(1)). Semantic events or displacement of objects determine the new states. Especially, the subsequent query depends on the granularity of semantic events. Semantic transitions should be adapted carefully. Nevertheless, eventual query may always work even if the granularity of states may differ. As future work, the continuity of user playing experience could be increased. The current system currently pauses the video for the user input. As future work, the querying engine may detect movement of objects and execute queries instantly without user interruption.

Synonyms

Interactive ray tracing; Ray casting; Real-time ray tracing; Recursive ray tracing

Definitions

Ray tracing – A rendering technique in 3D computer graphics that calculates the color of pixels by tracing the path that light would take if it were to travel from the eye of the viewer through the virtual 3D scene.

Video game – A video game is an electronic game that a player interacts with the computer using input devices such as a keyboard, mouse, game controller, mobile phone, or virtual reality headset.

Introduction

While ray tracing has been around for quite a while, it has only recently become a popular topic in the gaming community. With the recent introduction of process-effective algorithms, as well as other technologies; both software and hardware, it has become a much more viable option for rendering.

Starting with the basics, what is ray tracing? Put simply, ray tracing is a different form of rendering than what is typically used. Nvidia states that ray tracing "calculates the color of pixels by tracing the path that light would take if it were to travel from the eye of the viewer through the virtual 3D scene" (NVIDIA RTX Ray Tracing). In most use cases, this is impractical and time consuming due to an extremely large number of calculations. Because of the impracticalities of ray tracing, games require an entirely different rendering, a process known as rasterization. According to Michael Worboys (Worboys 2003), rasterization is a process where upon rendering 3D scene, triangle polygons which are translated to pixels on the screen. Though rasterization is far more efficient, it also has its drawbacks. Models must not be too detailed or the rasterization process takes longer, which is highly undesirable where 30 frames is a gaming community accepted standard minimum number of frames per second, disregarding stylized games which are intended to render otherwise.

Ray tracing in real-time was once thought to be the epitome of rendering hardware capabilities. This is because of how exactly ray tracing works. Ray tracing is when each pixel on the screen projects a line called a "ray" into a 3D-modeled scene. Each of these rays bounce off objects in the scene a specified number of times, gaining lighting and color information at each collision (NVIDIA RTX Ray Tracing). Due to the number of pixels on screens, the already intensive calculation process needs to be calculated over 2 million times per frame at a standard 1080p resolution. With a minimum of 30 frames per second, the math very quickly adds up. Ray tracing has been around for a long time now, however until recently, the renders could take hours for a single frame. Due to this, ray tracing was generally only used in film for special effects.

Graphics Hardware

The entirety of the gaming industry has primarily built hardware as well as software focused on the rasterization techniques that are now considered common practise. Due to the complex mathematical calculations, most of today's hardware is not suited for ray tracing. With the primary industry focus currently turning to ray tracing, old hardware is soon to become obsolete. While this is nothing new with computer electronics, older graphics cards were still able to be utilized over a long period of time due to a downgrade in graphics quality; however, with the introduction

of ray tracing, and the intensive calculations that come with it, this long period may become an abrupt wall of inaccessibility to the majority of hardware, currently in use by consumers.

Questions to Be Answered

Main Question How will the older generation of comparable graphics hardware perform when compared to the newer generation hardware built for ray tracing acceleration in a 3D modeling environment?

Secondary Question How will older and newer graphics cards compare when utilized in a game design environment as opposed to a 3D modeling environment?

Hypothesis

Hypothesis One As is typical of new hardware, the older generation of hardware will fall short when compared to the newer generation of graphics cards. The newer graphics card will increase performance by a substantial amount when measured in the same environments.

Null Hypothesis One The older graphics cards will hold their own when compared to the newer iterations of the same cards. Both cards will perform similarly overall when measured in the same environments.

Hypothesis Two When rending the same scene in a game development environment, the older graphics cards will fall behind in performance. The frame rate of the older graphics card will enable the scene to be unusable to effectively play, while the newer graphics card will show signs of playability.

Null Hypothesis Two Neither graphics card will render the scene efficiently. The scene in a video game environment will be totally unplayable. Unplayable in this instance refers to a frame rate well below the 30 frames per second previously discussed.

Terminology

Rendering – The generation of a two-dimensional or three-dimensional image from a model by means of application programs.

Ray tracing – A rendering technique in 3D computer graphics that calculates the color of pixels by tracing the path that light would take if it were to travel from the eye of the viewer through the virtual 3D scene.

Rasterization – Rendering an image via triangle polygons, which are translated to pixels on the screen.

Game industry – A catch-all term for any company or industry which has a stake in gaming as an industry. This includes, but is not limited to: graphics card manufacturers, video game console developers, and video game developers.

Hot-fix – A quick patch or update to fix a specific issue in software. These are generally used to fix bad software until the next major update is released.

Polygons – A flat plane made up of 3 vertices'.

Vertices – A point in a 3D environment. Two vertices make a line, and three make a face/polygon.

Ray casting – A process of using a straight line to check collision with objects in a scene.

Mechanics – A term used when referring to a component of a game which the player is able to utilize for one reason or another. E.g. jumping, climbing, and swimming.

Cost – The processing power required for a single task.

Frame rate – The speed at which frames update on the screen, typically calculated in Frames per Second (FPS).

AI – Artificial Intelligence.

Image noise – Unwanted artifacts in an image, typically only a few pixels large. This can also be referred to as "grain."

Post-processing – Manipulation of an image after it has been created.

Scene – A group of 3D models used to represent a digital environment.

Spatial volume – An allocation of space within a 3D environment.

Color bleeding – A slight reflection of color from objects which are adjacent.

Subsurface scattering – The manner in which light enters a translucent (semi-transparent) object which is then scattered or reflected.

Subdivide – Dividing polygons into more polygons. (ex. 1 polygon becomes 2 when subdivided 1 time).

Orthographic – A 2-dimensional representation of a 3-Dimensional object or space.

Perspective – A view from which shows height, width, and depth to accurately portray 3-Dimensional space.

Sample rate – The number of times a section of image is refined while rendering an image.

Material – An object surface data which tells the renderer how it should appear (ex. Metallic rough, or metallic reflective).

Review of Literature

The base principal of ray tracing has been around since the early days of 3D games; one of the first being "Wolfenstein 3D" by *ID Software* (Softworks 2012). *Raycasting* uses the same principals as ray tracing to calculate physics, and is currently utilized in countless games for *mechanics* based around physics, such as firing a weapon, or even calculating jump physics. These rays are used sparsely due to the cost of calculations. In practise, these rays are currently utilized hundreds of times a minute without much of a change in frame rate. The reason these are able to be utilized without much of a change in frame rate is because they usually only need a single collision. When compared to ray tracing, which always uses at least 1 bounce, requiring 2 rays; one to geometry and the other from geometry to the light source, the difference becomes apparent. This is why ray tracing was not viable until recently. Although noise and quality are greatly improved with more bounces, as the number increases so does the computational power necessary (NVIDIA RTX Ray Tracing).

Recent developments in software AI and recursion algorithms have enabled the Computer Scientists at Nvidia to create what they call an "AI-Accelerated Denoiser." What this does is takes image noise in and matches those pixels to the surrounding image to create a clearer image (Nvidia Turing 2018). More recent graphics cards produced by Nvidia are equipped with AI acceleration capabilities in the form of "Turing Tensor Cores" to assist in these de-noising techniques for use in combination with ray tracing (Nvidia 2018). With these AI techniques, the number of bounces each ray has to do is theoretically capable of being reduced to its absolute minimum of 1; however, the quality of image is greatly improved, even increasing that number as the AI has more to work with when creating the cleaner image. After the image is rendered, de-noising occurs during the post-processing stage before it is shown on the screen. This process is further expanded upon by a process called Deep Learning Super-Sampling (DLSS) if ray tracing is being performed on Nvidia RTX card. DLSS essentially takes pre-calculated improvements to visuals and applies them to the ray tracing process, allowing an increase in frames per second (Nvidia 2018).

As it stands, Nvidia appears to be the leading authority in ray casting due to the amount of information readily available, however; AMD, another authority in ray tracing technology, seems to primarily use a technique called Bounding Volume Hierarchy (BVH) to accelerate Ray Tracing. Through segmenting a scene dynamically into spatial volumes, the required data to calculate each ray is reduced (AMD Radeon ProRender).

Difference in Quality

The largest difference between rasterization and ray tracing is that as you increase polygons in a rasterized scene, the computational power necessary also increases (Worboys 2003). In ray tracing, the main computational increase primarily occurs when the number of ray bounces is increased; however, this does not mean that

polygon count is ignored as the more polygons; the more complex the bounces need to be to render the image. This means that while tricks can be utilized to create insane levels of detail with rasterization, they would not be as necessary with a full ray tracing rendering system. Color bleeding and subsurface scattering are also traits which are time-consuming to create with rasterization but are inherently available with ray tracing (Nvidia 2018). These are created naturally by the bounce process of ray tracing and create a much more realistic and immersive look for games.

Methodology

With the industries focus turning to ray tracing as a standard for graphics rendering, the graphics hardware consumers currently going to be obsolete at a much quicker depreciation rate. Due to the complexities noted earlier in this article, current hardware may not be able to handle the changes to come; at least not nearly as well. Thankfully, the graphics and gaming industry has gone through changes like this before, which can be examined and compared to this change in the industry.

The examination can be conducted in two stages. The first stage is based on an experimental build (v. 2.82) of Blender (Blender.org), which was used to construct two different 3D scenes. The experimental build was decided upon due to the lack of compatibility for utilizing the turing cores in the officially released version as of the writing of this article. All stages were run on two different generations of graphics cards with the same performance level for a better comparison. The GTX 1060 represents the lower-end graphics card, and the RTX 2060 represents the higher-end graphics card.

The first of the two scenes constructed was a plane subdivided, so it contains 1,048,576 faces. The vertices' heights were then randomized based on a noise image generated in Blender. This gave the plane details such as shadows and depth. A material resembling hard plastic was then applied to add complexity to the render. This was then rendered in a 4 K × 4 K resolution (4098 × 4098) orthographic perspective top-down view. This same scene was then rendered from a perspective viewpoint originating from a corner of the square in a typical 4 K configuration (4098 × 2160). These renders were then rendered multiple times using different sample rates to find the sample count, where increasing said count any further would not return any better results. After the optimal sample count was found, the scene was rendered from each perspective for a final time on each graphics card, and the time to render was recorded based on the graphics card utilized.

The second scene was created by adding in more complex effects such as water reflections as well as transparency to various objects. Its polygon count was higher as well, sitting at around 6.6 million polygons. This scene is referred to as the island scene, as the focus of the scene is a lone volcanic island covered in stones, grass, and palm trees, which is surrounded by an ocean. The ocean adds an additional complication as it is rendered by altering how the rays reflect off of the surface of the water throughout the 5-second animation. The first frame of The island scene was used as a reference point when comparing the render times to the full rendered animation. The render times for both the single frame and the full animation were recorded for each graphics card, and this concluded the first stage.

The second stage takes the island scene and places it in an experimental build of the Unity3d Game Engine (Unity.com). Again, the experimental build (v. 2019.3.0b8) was chosen due to ray tracing being inaccessible in earlier versions. After importing the 3D models for the environment and recreating the scene as it existed in blender, the materials for every object had to be recreated for unity. After the scene was complete, it was run on both graphics cards. A script was then implemented to calculate the average frames per second; this is the data which was recorded. As a final step to challenge the existence of ray tracing in gaming, the scene was optimized by cutting the polygon count in half to about 3.3 million, and the frame rates were re-recorded.

This optimization was made because the polygon count in games tends to be highly controlled based on various conditions, and the high polygon count used in the blender scene does not accurately represent a typical game environment's optimization. The high polygon count data is still useful as it represents an extreme use case of a non-optimized game environment, which occasionally happens. All data collected using the methods described were then compared and analyzed in the following sections.

Data Analysis

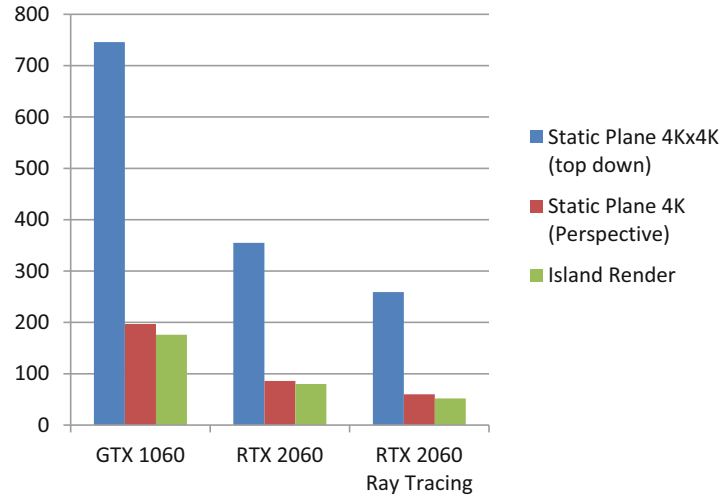
The collected data is intended to test the reliability of ray tracing in game design. With the standard of rasterization in video game rendering closing the gap between digital and reality, is Ray Tracing the next stage of graphical processing in gaming?

There were two main stages. The first stage explored the 3D environment blender for rendering scenes and animations at various levels of detail and comparing the render times. Each scene in the blender is progressively more complex with the amount of detail involved in rendering the scene. Each render's details were recorded, as well as how long the scene took to fully render. The purpose of this stage is to set a baseline with which the second stage can be compared to, as ray tracing has been utilized in rendering and animation for videos and films for some time.

To begin, Fig. 1 shows the render time of the static images in seconds. This data indicates a decrease in the time it took to render each image, additionally, all of this data was collected while rendering the scene in a ray traced environment. It is important to note that "Performance" is defined by the time it takes to render the given scenes. The GTX 1060 graphics card performed the worst between the two cards. The RTX 2060 has two different times on this graph due to it having "Turing Cores"; one measurement utilizes the cores, and the other doesn't. This shows a difference in render capabilities on the same hardware. The data marked "Ray Tracing" is utilizing the Artificial Intelligence capabilities for the rendering, and it greatly decreased the time over the GTX 1060, although the raw performance of the RTX 2060 alone was a significant increase in performance in all renders. The equation below calculated that the performance was increased by 71.03% between GTX 1060 and the basic RTX 2060 in the top-down static plane image.

$$\frac{|V_1 - V_2|}{\left[\frac{(V_1+V_2)}{2}\right]} \times 100$$

On that same render, with the turing cores introduced, the RTX 2060's performance

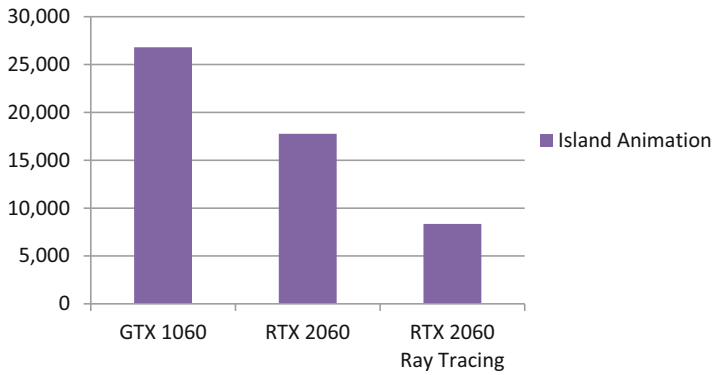


Ray Tracing in Video Games, Fig. 1 Static render times in seconds

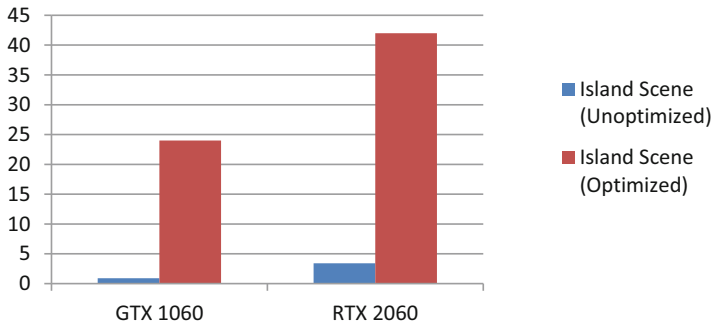
increases an additional 31.27%, creating a total performance increase of 96.92% between the GTX 1060 and the RTX 2060 utilizing the turing cores. The perspective render of the static plane boasted similar results in performance increase, with a 78.45% increase between the GTX 1060 and the RTX 2060, and an overall increase of 106.62% after utilizing the turing cores. The static island render proved to see very similar performance increases of 75% between the two base cards and an overall increase in performance of 108.77% after introducing the turing cores.

The next graph, Fig. 2, shows the differences in time for the animated island scene. Again, the GTX 1060 underperformed compared to the basic RTX 2060. The RTX 2060 had a 40% increase in performance over a total of 150 Frames in the 5-s animation. Utilizing the turing cores, the RTX 2060 increased another 72.14%. This creates an overall performance increase of 105.04% between the GTX 1060 and the RTX 2060 cards. This concludes stage one. Stage two involves running the same island scene in a Unity3D, a game engine environment while utilizing Ray Tracing.

This stage compares the frame rates in both systems under two different conditions, as shown in Fig. 3. The first condition is an unoptimized island scene, the same scene rendered in blender with minor modifications. Due to draw distances, the ocean was reduced in size as it was not fully rendered anyway. The polygon count of 6.6 million is very high for an environment in a game engine; even what is considered a "high" number is dependent on which game engine is being utilized, as well as project requirements for polygon counts. The second condition consists of the island scene, which has been more optimized to run in a game engine. By reducing the triangle count by half to 3.3 M, the results increased dramatically on both graphics cards. The results in this stage are recorded in frames per second, or FPS. The FPS count is directly related to the performance output of each graphics card; the higher the FPS, the higher the performance.



Ray Tracing in Video Games, Fig. 2 Kinetic Island render times



Ray Tracing in Video Games, Fig. 3 Game engine frames per second

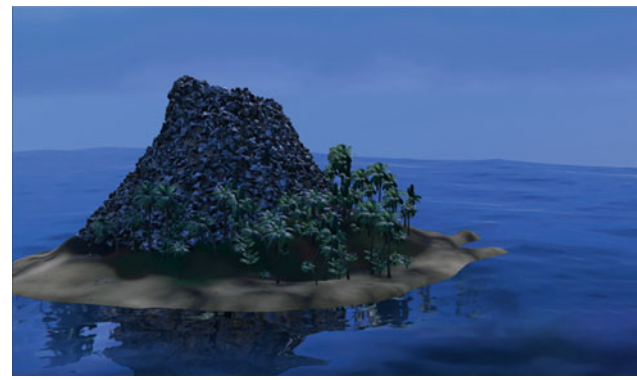
Starting with the unoptimized scene, the GTX 1060 was able to render the scene at a steady 0.9 FPS. This implies that each frame takes just over 1 s to render. Following that, the RTX 2060 was able to render the scene at an average of 3.4 FPS, or around 1 frame every 294 ms. While this does not seem like a large difference, it is a 116.3% increase in performance. In the optimized version of the island scene, the GTX 1060 rendered the scene at 24 FPS, or about 42 ms per frame. While the animation appears smooth, it is still unacceptable by most gaming standards. The RTX 2060 rendered the scene at 42 FPS for an overall increase of 54.55% in performance while taking an average of about 24 ms to render each frame.

Overall, the results drastically varied between the 3D environment results and the game design environment. While the 3D environment results are much clearer and color correct (Fig. 5), the game design environment does succeed in producing very similar results as shown in Fig. 4, although it is darker overall. The following section reviews the data collected as well as discuss conclusions and other implications (Fig. 5).

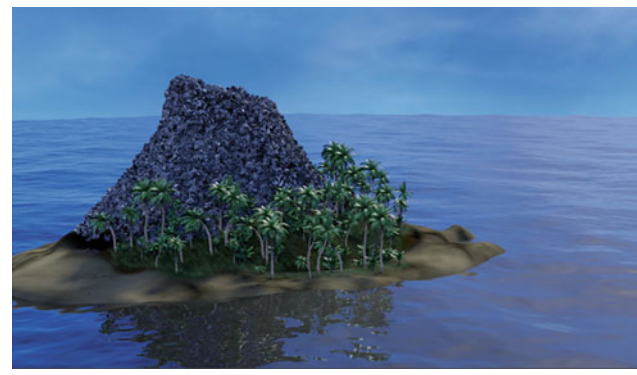
Conclusions

The initial limitation is the lack of current data. Due to the topic being so recently viable, large-scale data evaluation in the current state of the gaming industry is unavailable. In conclusion, however, the data recorded looks to be very promising overall. The data indicates large increases in performance after switching to the RTX 2060 graphics card. It aimed to test the reliability of ray tracing in game design. The render times and frame rates reveal that the performance increase from the GTX generation to the RTX generation is substantial even without utilizing the Turing Cores for enhanced Ray Tracing performance.

The first question asked how the older generation of graphics card compares to the newer generation card when compared in a 3D modeling



Ray Tracing in Video Games, Fig. 4 Unity environment first frame



Ray Tracing in Video Games, Fig. 5 Blender environment first frame

environment. In each test utilizing the 3D environment, the RTX 2060 outperformed the GTX 1060 by at least 70% before the turing cores were introduced. Upon Introducing the turing cores to enable the ray tracing Acceleration, all of the renders for the RTX 2060 saw a substantial increase yet again in performance. This data confirms the first hypothesis. The newer hardware completely outperforms the older hardware, and the turing cores add insult to injury with the extra performance boost.

The first stage tests were necessary to form a frame of reference when comparing the data to the frames per second information garnered from the game development environment. When referring to the data from the first stage, it is important to note that each frame took multiple seconds each. For the full animation of the island, 150 Frames, the absolute quickest time to render the scene was still over 2 h long, averaging about 55.64 s per frame. This exact same scene before any optimization was able to render in the game development environment at around 0.9 frames per second at best with the GTX 1060. This means that calculating each image of the animation took about roughly 1 s on average when utilizing the GTX 1060 graphics card. The performance increases to 3.4 frames per second at best with the RTX 2060, resulting in a render time of 294 milliseconds for each frame. These numbers when compared to the render times for the 3D environment show astronomical decreases in the amount of time it takes to render each frame. Neither graphics card renders the scene in its unoptimized state effectively enough to meet any gaming standards. While the RTX 2060 outperforms the GTX 1060 by 116%, it is considered to be comparable quality when compared to each other. In this instance, the second null hypothesis is the accepted hypotheses. This is due to neither frame rates being actually playable, though the image quality stays constant between both graphics cards.

The final set of data saw an optimization of the island scene. Reducing the polygon count by half, allowed both graphics cards to increase frame rate dramatically. The GTX 1060 was able to render the scene at 24 frames per second, where the RTX 2060 was able to render 42 frames per second. These numbers show that gaming while utilizing ray tracing is definitely possible. The older graphics card was able to reach 80% of the accepted minimum frame rate, while newer graphics card performed well beyond the minimum of 30. After the polygon optimization, the RTX 2060 outperformed the GTX 1060 by 54.55%. Though these optimizations did not take into account occlusion culling wherein the objects in the scene dynamically exclude themselves from being rendered when not in view to speed up render times, with further optimization it is believed that the GTX 1060 could run above the minimum frame rate. In this instance, the second hypothesis is the accepted hypotheses. This is due to the large gap in frame rate between the graphics cards. Although further optimization would better the results of both graphics cards to above the minimum frame rate of 30, the gap between the graphics cards would only grow larger as the RTX 2060 would more efficiently be able to utilize the turing cores.

This successfully tested the reliability of ray tracing in game design. Nevertheless, if this were to be performed again, some things would need to be changed. First off, all programs utilized were in Beta release, meaning they were not officially released at the time of writing this article. This means that the programs may not have been optimized or even fully utilizing the ray tracing capabilities of the RTX 2060, which could possibly skew the findings. The Beta releases were used due to lack of implementation for ray tracing acceleration in the official releases of these programs. The second thing which should change or be improved is the optimized island scene could be further optimized to better represent a scene from a game utilizing level of depth models as well as dynamic occlusion which was previously mentioned. As it stands, the scene is a good representation of polygon count in a gaming environment; however, game engines allow much more optimization, which would drastically increase all frame rates. Though the data is far from conclusive, it indicates that at the very least ray tracing in video games is a definite reality, and though the newer graphics cards will perform far better than older models, the older models may still have a

life to live as the focus shifts to ray tracing as a means of rendering.

Raycasting in Virtual Reality

Krzysztof Pietroszek
Game Research Lab, School of Computing and Design, California State University Monterey Bay, Seaside, CA, USA

Synonyms

3D pointing; Distal pointing; Virtual pointing metaphor

Definitions

Raycasting is a set of interaction techniques used in immersive environments for selection of targets at the distance. Raycasting resembles real-life pointing with a laser pointer: the user points a ray of light at the target and confirms its selection with a motion gesture, a voice command, or a button click. Raycasting belongs to a family of interaction techniques known as virtual pointing. A more general term, 3D pointing, includes raycasting as one of the common approaches to selection of objects in immersive environments. The term "raycasting" should not be confused with the term used in computer graphics to describe a rendering technique.

Introduction

Object acquisition is a prerequisite for object manipulation in 3D user interfaces (Bowman et al. 2017). Target acquisition technique must facilitate the indication of an object and confirmation of its selection. It should also provide visual, haptic, or auditory feedback during the selection task. A popular technique to realize target acquisition is a family of raycasting techniques. Raycasting borrows the familiar pointing using a laser pointer adapting it for acquisition of 3D objects in an immersive environment.

The Family of Raycasting Techniques

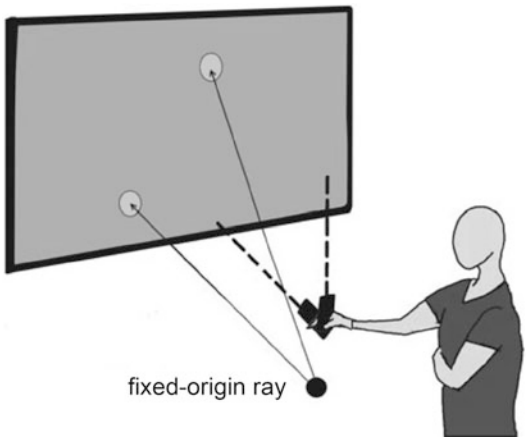
One of the earliest examples of raycasting techniques was called "laser gun" and was introduced by (Liang and Green 1994). Since then, many raycasting techniques were developed for a variety of input devices (Argelaguet and Andujar 2013). A number of specialized raycasting techniques were also developed to address challenges of 3D interaction, such as accuracy and speed trade-off, occlusion, or target density. Common modifications of the technique include adjusting the shape and the size of the selection tool or the shape and the number of rays. Some techniques combine a ray with a 3D point cursor that is contained along the ray.

Notable examples of raycasting techniques include Depth Ray, Aperture Selection, 3D

Bubble Cursor, and Fixed-Origin Raycasting. In Depth Ray (Grossman and Balakrishnan 2006) from all objects intersected by the ray, the one that is closest to the 3D cursor that moves along the ray is the one that is selected. In aperture selection technique (Forsberg et al. 1996), user can manually adjust the selectable areas apex angle. In 3D Bubble Cursor (Vanacken et al. 2007), the size of the spherical cursor at the ray's end expands or shrinks automatically to reach the object closest to its center. In Fixed-Origin Raycasting, the ray originates from a fixed point, rather than the user's hand or input device (Jota et al. 2010; Pietroszek et al. 2014). A comprehensive survey of raycasting techniques was recently published by (Argelaguet and Andujar 2013).

Input Devices

Typically, raycasting requires an input device providing six degrees of freedom (DoFs) – rotation and translation along all thee axis – in order to provide user with full control over the position of the ray origin and the rotation of the ray. High-precision handheld input devices used to implement raycasting include air mouse, magnetic tracker, Oculus Touch tracker, HTC Vive Controller, and PlayStation Move controller. For casual, equitable 3D interaction, techniques utilizing a smartphone or a Wiimote were developed (Pietroszek et al. 2014, 2015). Raycasting can also be realized as a freehand interaction using optical hand tracking, ranging from high-precision motion capture systems, such as VICON or PhaseSpace, to low-cost systems such as Leap Motion and Microsoft Kinect. Alternatively, wearable input devices may be used, including motion capture suits (e.g., Perception Neuron suit), off-the-shelf smartwatch (Pietroszek et al. 2017; Kharlamov et al. 2016), electromyographic sensor (Thalmic Myo), or digital gloves (Senso glove). When the input device does not provide six DoFs, fixed-origin raycasting techniques can be used as an alternative (Jota et al. 2010; Pietroszek et al. 2014), as it requires only three DoFs (Fig. 1).



Raycasting in Virtual Reality, Fig. 1 Smartcasting (Pietroszek et al. 2014): an example raycasting technique using off-the-shelf smartphone as an input device

Conclusion

Raycasting is a family of popular interaction techniques for acquisition of objects presented in virtual reality systems or on large screens. Raycasting techniques offer good accuracy and speed trade-off for 3D target acquisition and a variety of approaches to solve 3D interaction challenges, such as occlusion, fatigue, or high density of objects. For object selection at a distance, Raycasting is de facto a standard 3D selection technique in immersive environments.

Redesigning Games for New Interfaces and Platforms

Cetin Tuker
Graphic Design Department, Mimar Sinan Fine Arts University, Istanbul, Turkey

Synonyms

Adaptation; Crossplatform; Porting

Definition

Redesigning games for crossplatform adaptations and new interfaces (crossplatform game redesign) is to redesign the interface, interaction, user experience (UX), game mechanics, rules, assets, and even the narrative and genre of a game which already existed in its native platform, to fit in the needs, abilities, potentials, and predictions of the new (ported or migrated) platform.

Crossplatform game redesign is a broader range of spectrum than game adaptation, between the two extreme points of the original game itself (a game which was designed in its native platform) and a completely different game (a game which is designed in another platform with a different narration, gameplay, rules, assets, UX, and interface).

Introduction

In the competitive bussiness world of digital games industry, there are many gaming platforms, and these are not identical. There are various gaming platforms developed with several technologies at different decades by different manufacturers. Some dedicated gaming platforms are very small in size to be portable and some are large and powerful machines to drive large screens with high-resolution images. These powerful ones may also be supported with complicated peripheral devices to scan and capture gamers body posture and hand gestures as an input for the gaming interface. Personal computers, mobile devices like mobile phones, tablets, and phablets are also some of the most popular and highly penetrated gaming platforms owned by the most gamers although they are not dedicated platforms for gaming. Virtual reality (VR), augmented reality (AR), and mixed reality (MR or XR) systems also exist with their special headsets.

Light weight handheld paltforms have to overcome the problems of prize, weigt of hardware, battery consumption, and heat while offering optimized quality graphics, enough CPU/GPU power to run games, ergonomics (geometry of the console) to comfortably fit in the hand of the player,

easy to reach buttons, and sometimes feedback systems with sound and vibration. Personal computers are mostly equipped with a mouse pointer, a keyboard, and a flat screen. Mobile devices use touch screen controls which offer a very different interface system with taps and swipes and VR, AR, and MR devices offer interface systems with hand gestures, walking platforms, pods, etc. with the result of an altered user experience.

Game producers develop games for several different platforms. When a game achieves succesful sales figures on a platform (example: on personal computers), producers can decide to port this game to another platform (example: mobile platform) to gain more sales. At this point, depending on the needs of the game, sometimes, game's interface can present difficulties to fit in the target platform and although the new hardware can run the game smoothly, players can complain about the playability of the game. In some cases due to the inconsistencies between the game mechanics and interface, some games can become nonplayable. This can force game designers to redesign the game from scratch or even design a completely new game inspired from the original. The act of redesigning needs further detail and explanation.

The rest of this article is organized as follows: first, background information about basic definitions related with adaptation, remediation, and interfaces will be presented; second, the reasons why crossplatform porting and redesign processes are needed in digital games will be explained; third, dynamics and levels of redesign processes will be presented in detail; and finally, some case studies to illustrate the theories in previous chapters will be presented.

Background Information

Video games are designed to be played on specific hardware platforms. Definition of the word "platform" is mostly based on the context and domain. In transmedia context (transmedia storyteling: Using different media platforms to tell the different parts of one giant story across time. Audience is actively involved and contributes to the narrative by adding content), a platform is "something that supports the channel & media such as YouTube, Soundcloud, Flickr, a shopping mall, a cinema, a web site and so on" (Pratten 2011). In video games domain, a game platform is an environment including software and hardware components which is designed specially for running video games, shortly a console. Platforms naturally define and exist with their specific hardware and interfaces to interact with human beings.

A game console is a special hardware developed to run video games. It includes hardware and software components (a special operating system) with their own technical specifications and limitations. A game console mostly runs games only designed and developed for the specific platform. Specifications and limitations of the hardware also defines the interface and how human computer interaction (HCI) occurs. Consequently, HCI and interface will determine the UX.

In general, interface is the shared boundary between two or more media. In video game context, interface includes hardware, software, and graphical componets which are used for interaction, input, and output. Particularly these are (1) the graphical user interfaces which are seen on the screen, (2)touch screen surface of the device, (3) a mouse pointer, (4) keyboard, (5) game pads with several designs, (6) buttons located on the handheld console, (7) clickers – to use with MS Hololens, (8) VR, AR, MR headsets, (9) cameras, and (6) microphones which can scan the movements and record voice of the gamer as an input source which can be used to interact with the game. Interactivity is a kind of communication in which a message is related with a number of previous messages and relationships between them (Liu and Shrum 2002). In video game context, an example of interaction is controlling a game character by pressing the keys on the keyboard or on a gamepad (interface). Every key is mapped to a special animation of the game character; when a player presses a specific key, it triggers the mapped animation. Results of this interaction is processed by the game system and transferred to the screen (another form of interface) so that the player can decide the next move.

Therefore, in video game context, interface acts as a translator between human and game system. It conveys human behavior, language, gestures to data that can be understood and processed by the computer. In return, the computer conveys and translates results of the processed data coming from game system to information which can be understood and processed by the player.

Essentially, an interface cannot translate transferred information identically between media. Rather, it transforms or interprets gamers' actions and choices to a form in which the game system can understand and process. The degree of exactness, level of similarity, or distance of the interpreted message to the original message can be named as fidelity. As an example, a player mostly interacts with a first person shooter game (FPS) which is running on a personal computer by using WASD keys on the keyboard and keys and movements of the mouse pointer. In this case, the camera in the game world is transformed into the identity of the player's eyes. Player sees the game world with the camera located in the game world. Game camera is also the transformed personality of the game player. Movement of the camera in game world is the movement of the player. By pressing the WASD keys on the keyboard, the player moves or walks in the game world. This is not a translation, instead this is a transformation or interpretation of the reald world action to the game world action with some level of fidelity. Player is not actually walking in the real world to interact with the game, instead she presses the keys and assumes she is walking. Consequently, the game system interprets the keystrokes as the movement of the game camera and game character as they are mapped to predefined actions decided by the game designer.

The technology used by the game interface affects the level of interpretation or transformation, in other words fidelity. In general, technology is systematized practical knowledge that improves productivity (Seels and Richey 1994). In computation context, this term is mostly used as the objectified state of the knowledge or the hardware and software components and the architecture of the system. Therefore, in video game context, an interface technology is the objectified state of the knowledge to design and develop the interface between the player and game system.

Ergonomics is a cross-disciplinary field and, generally, it is the study of the relationship between people and their environment, especially the equipment they use. As it is a cross-disciplinary field, other disciplines such as psychology, engineering, biomechanics, industrial design, physiology, and anthropometry have contributed to the field. Shortly, the act of designing equipments, devices, and processes that can fit the human body dimensions and its cognitive abilities is in the domain of ergonomics. In video games domain, ergonomics can be defined as the study of the relationship between the player and interface, game mechanics, game console geometry, and environment in which the gaming system is located at.

Crossplatform Adaptation of Video Games

Occasionally, preexisting narratives are remediated to different video game platforms (Remediation: The representation or migration of a narrative that was originally created for one type of media to another new type of media or by incorporation of existing and the new media). This phenomenon is called adaptation. According to Flanagan's (2017) definition, adaptation is the movement of textual material from one medium, platform, delivery method, time, or cultural context to another.

This is similar for video games. Video games can be adapted or migrated from one platform to another. This can also be called as crossplatform adaptation. In computing domain, a crossplatform software is a computer program, game, or other content that can run on multiple hardware platforms. Flanagan (2017) encounters four types of adaptation related with digital games: (1) adapting virtual worlds described in original narrative to a digital game world by creating or visualizing the universe as digital and interactive game environment; (2) porting of an existing digital game from one gaming platform (console) to a new gaming platform considering the fidelity of design of

game, assets, mechanics, rules, and UX while optimizing for the hardware needs of the new platform; (3) localization, translation, and cultural specificity while adapting the digital game from one culture to another culture; and finally (4) modding, which is "... the player centric adaptation of game assets, usually through level editing tools released with specific games" (Flanagan 2017). While modding a game, players use level editing tools, existing assets, and game engines to design and develop their own game maps or levels, they can even create new games with new narrative by extending the abilities of the supplied game code, assets, and engine.

Why Crossplatform Redesign Is Needed

Frequently, video games are designed to run on specific platforms, and this choice, which was made by the design and production team in the very beginning of game design process, sometimes alters the narrative, predicts human – game interaction, ergonomy, usability, UX, and also game mechanics. When an existing game is ported from native platform to another hardware platform, the game has to fit and run in the new platform with a different interaction system and hardware specifications, and the change of interaction system will create a different UX. If the aim is running the game on a very different platform such as crossplatform adaptations between personal computer, console, VR, or mobile devices, whole game experience, interaction mechanics, ergonomy and player comfort will change.

The difference between the original interface and target interface can be named as "distance." If interfaces are similar (like a personal computer running on Windows, MacOS or LINUX operating systems, and equipped with common peripherals like a mouse pointer and a keyboard) than the distance between interface systems are small. If original and target interfaces are very different (like Nintendo Game & Watch and Microsoft Hololens) than the distance is large. Different hardware can cause different UX due to their difference of interfaces with various distances to the experince created by the original video game. At some point, the distance between the ported video game and the original video game becomes too much that the ported video game will not give the same feeling of the original or the ported video game becomes unplayable or it can be very difficult for the player to play the game (Fig. 1).

Depends on the platform, player will need some more or less interaction. This can lead to a need of a radical change of the game mechanics and redesigning the gaming experience. At this point, there is an urge to redesign the game mechanics according to the needs of the new platform. Most of the times this can lead to a change to game mechanics and rules or can create an opportunity to design a new game with the inspiration from the original game.

Redesigning in More Detail

Redesigning is the act of designing an existing product partially or completely from scratch due to the changes in factors and needs which made the existing design partially or completely obsolete. In video game domain, some examples to these factors and needs are the differences and developments of interface technologies and new features added to the game systems.

Here, the difference between a remake, clone, and redesign must be emphasized. A remake is adapting the same narrative, same game mechanics, and rules to a very similar or the same platform featuring, mostly, newer technology. A popular example of a remake is Black Mesa (Crowbar Collective 2012): a remake of Half Life (Valve 1998). Original title, Half Life, was released in 1998 for the widely used personal computer technology of the time. Producer continued to extend the story as a sequel with Half Life II (Valve 2004), Lost Coast (Valve 2005), Episode I (Valve 2006) and Episode II (Valve 2007). A sequel is an addition to the original story in forms of a movie, literature, drama, television show, a song, or video game that develops the existing story in the same media channel with the exiting story. Sequels are usually in the same fictional universe with the original work and chronology of narrative follows the original product.

Given: An existing video game (with or without narration)
Target: A new platform (with or without a dedicated device or no device) other than the original platform.
Independent Variables: Interface technology, interaction method, platform.
Dependent Variables: User experience, playability, game mechanics, genre, game rules.

Amount of Redesign

Redesigning Games for New Interfaces and Platforms, Fig. 1 General scheme of redesigning games for new interfaces and platforms. (Image created by the author)

For the HalfLife case, the title become so popular that a fan group decided to develop a remake of the first part of the sequel as Black Mesa with new technology and tools supplied by the producer. Narrative and game mechanics were same with the original and, due to the new features of the new technology, game assets were created from scratch with fidelity (but with more detail) to the original. To remind, in game adaptation context, fidelity is the degree of exactness or level of similarity of the ported or the redesigned (hypertext) game to the original or the native game (hypotext).

A clone in video game context is a video game or game console which was heaviliy inspired by or very similar to the original video game. The term usually used with negative meaning for the games whose producers tries to profit off the original games popularity and success and for games that have a lack of creativity or originality.

Finally, redesigning is a spectrum, typically provoked by adapting or especially crossplatform porting, between two extreme points. These are remakes of the same game with very little redesigning, with very high fidelity to the original game, and designing a new game from scratch inspired by and resembling the original at some level. There is always an existing video game with or without a narrative given as a starting point and targeting of a new platform with or without a dedicated device. Independent variables predicted by the target platform, the variables that game designer can not chose, are hardware capabilities, operating system, interface technology, and interaction method. As these are different than the source game, dependent variables are user experience, playability, genre, game mechanics, and rules of the ported game.

Levels of Redesign Processes for Crossplatform Video Games

It is possible to describe five main levels of redesigning. First one is porting the original game to a similar platform. An example of this is porting between Windows, MacOS, and LINUX operating systems running on almost same hardware. Interface and interaction systems are almost the same on these systems, narrative (if any exist), game mechanics, rules, and user experience can work almost the same after porting. This leads to same level of playability on all these systems. Altering controls between keyboard and mouse pointer to game pad can change user experience at some level, but this will not lead to major changes. As popular game engines support all these platforms at the same time, there will be almost no to very little additional programming. Porting from one of these systems to a game console like PlayStation or XBOX also will not lead to radical changes as their hardware and interfaces can support or are compatible with the original game.

Second level is porting a game between uncompatible game hardware. In terms of interaction technologies: PCs typically use keybords, mouse pointers, and game pads; mobile systems use touchscreens; VR, AR, and MR devices interacts with the user through a wide variety of gestures and handheld controller collections; retro handheld consoles use low resolution screens and small buttons scattered around the console; and some game systems can detect body geometry and movement for interaction among other interaction techniques. With this variety of interface and hardware technology and interaction methods, it is not possible to create an exact translation between every platform. Some game mechanics may not work, some part of narrative may not be expressed, original games genre (e.g., 3D FPS) may not fit in the target equipments hardware (e.g., not supporting 3D). In some cases, the hardware can support game engine, but the user interface and interaction methods can be very difficult to adapt.

An example for this is porting a game from a mobile system to a mixed reality system. A mixed reality system can interact with the physical geometry of the surrounding real world environment. This can also add some additional interesting features to a game like letting the player move in the game environment and explore the game in 3D. However, the same system can not support a game pad with buttons and a touchscreen. Technically, a game which was designed to run with a

touchscreen interaction can run on a MR system, but the player cannot interact with the game so game mechanics and experience will either not work or will be very different. Therefore, game designers may need to return to the design stage and start redesigning the game to fit in the target platforms' need and features.

Third level is the extreme zone of the second level where the ported game is not playable anymore because of the inconsistencies between the original and target games hardware, interface, ergonomics, or graphical needs. In some cases, the game can run on the target hardware but players will not prefer to play the game because of these inconsistencies.

At fourth level, redesigning becomes the only way to make the game playable again. Designers can be inspired from the original game, and they can still try to design a similar game. Narrative can be the same or very similar to the original. To satisfy the needs of interface technology, ergonomics, interaction methods, and other features of the target platform, designers can change the game genre, rules, or game mechanics. Therefore, user experience will be very different from the original game. This is not a translation but a completely different interpretation of the original game.

Last level is where designers can be inspired from the original game and design a different game by using the main or totally different game mechanics and rules. The new game may resemble the original game in some sense but for the player it will be obvious that the two games are more different than similar. At this level, there may be no identifiable relation between the narratives of the hypotext and the hypertext. Resemblance may be at the visual level (e.g., using some simiar visual game assets), game rules, or mechanics of the original game.

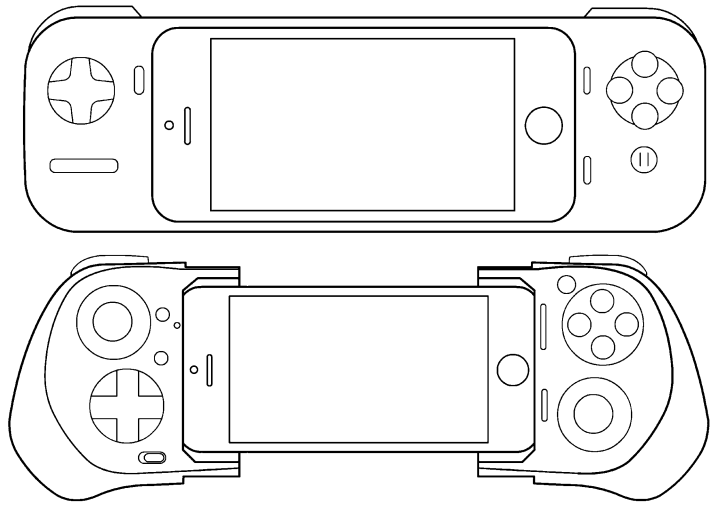
Case Studies

Crossplatform Porting Can Have Negative Effects on Playability

As penetration rate of mobile phones increase in the market, game producers started to port their existing famous titles to several mobile platforms. A mobile platform actually is a pocket-sized general-purpose computer with its special hardware features and limits, interfaces, and own operation systems. App stores contain a lot of general-purpose (word processors, photo scaners, painting software, music players, etc.) software to be installed on a mobile sytem. Games are just some part of these software collection. Most of these systems can also run a software to make telephone calls. So a mobile phone can be counted as a computer more than a telephone. Depending on the size of the hardware, these systems can be called as mobile phones, phablets, or tablets. Mobile systems mostly use touch screens as the interface.

In the mobile platform domain, touch screen controls and swipe gestures can be handy for dialing numbers and making calls. However, for playing games, a touchscreen surface is not an ergonomic choice since it does not provide the physical feeling and feedback of a keystroke or a game pad. This swapping of interfaces can affect the game play experience of the player drastically and even result in a nonplayable game. This can be resulted even with a nonplayable game. Some third party producers developed controllers to mount on the mobile phones to facilitate a gameplay with better ergonomics, feedback, and gaming experience. Logitech PowerShell (Narcisse 2013) and MOGA Ace Power (Fahey 2013) are some of these add-ons (Fig. 2). Some manufacturers even produced bluetooth gamepads to work with mobile platforms. However, these game pads can have compatibility issues with some hardware and games. This can make the game nonplayable.

One of the games whose playability was drastically affected due to the crossplatform porting is Grand Theft Auto III San Andreas (Rockstar Games 2004). GTA is an action adventure, open world, free roaming game in which the player can either follow the scenario and narrative by completing the assigned tasks sequentally, or can complete optional tasks, or experience the city simulation just by walking or driving around the streets of the virtual cities. San Andreas was ported to IOS in 2013. While the PC and console



Redesigning Games for New Interfaces and Platforms, Fig. 2 Examples of add-on game controllers for some smart phones. (Image created by the author)

versions of the game use keyboard controls or game pads, the mobile port was originally designed to interact with the touchscreen. Touchscreen controls are not precise and smooth enough like keyboard controls because of the ergonomic issues between the human hand and the screen. As a result, players complained that it is very difficult or near impossible to complete some of the tasks (Johnson 2013).

The New Platform Can Create Serious Ergonomic Issues

Virtual Reality systems are not new inventions, but as the hardware systems developed to enable more precise and faster detection of an object's position, acceleration and rotation in space, more immersive experiences became possible with cheaper and light-weight systems. Depending on the features of the VR system, a player can experience an immersive world while sitting on a chair or walking freely in a limited part of the real world within the ranges of the sensors. Player can interact with the game through the body movements, gestures, and by pressing the buttons or trigers on the handheld devices. These kinds of interaction modes promise a more immersive experience to the game player, which is closer to the feeling of the real world.

The game world is still not the real world, and VR systems still cannot match with the human balance system. Human balance system is a combination of vestibular organs, eyes, skeletal muscles, and joints equipped with sensory receptors. All these send information to human brain about the current position and balance of the body. If some part of this information is missing, incomplete or inconsistent with the other sensory information, issues like nausea and dizziness can occur, which can make the game nonplayable although it can run on the computer system smoothly.

An example of this is The Elder Scrolls V: Skyrim VR (Bethesda Studios 2017). Several players and game critics mentioned that the VR experience created with this game and several other VR games ported from their original native platforms, mostly PC and game consoles creates strange feelings, nausea, and dizziness. In these examples, VR does not add more playability to the game but instead converts it to some kind of an "elaborate armchair tourism" (Alexandra 2017; Fussel 2017). Fussel (2017) also directly criticizes that playing a VR game while sitting on the chair adds nothing to the game play that was originally designed to play while sitting on a chair but looking at a flat monitor instead of a 360-degrees surrounded environment.

Redesigning the Game for Crossplatform Porting

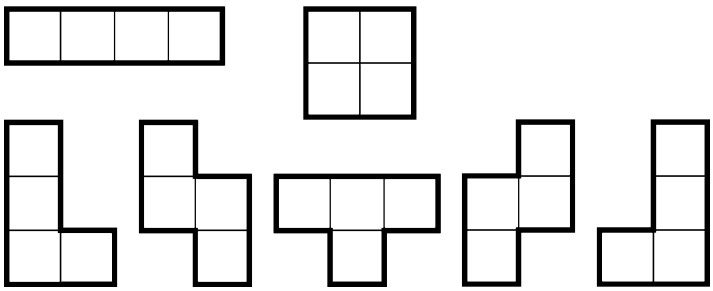
Tetris is one of the most frequently cloned, remade, and ported digital games of all times. Almost every digital game console has a variation

of Tetris. The original game was designed and developed by Russian game designer Alexey Pajitnov, Dmitry Pavlovsky, and Vadim Gerasimov on an Electronika 60 computer and released in 1984 (Gerasimov 2018). Tetris is a tile matching puzzle video game. The whole game contains seven types of puzzle pieces (called as Tetriminos meaning "Tetris Bricks" – Gerasimov uses the word "tetramino" instead in his website.) and all pieces are made by combining four equal sized square units (called tetrominoes meaning a geometric shape composed of four squares) (Fig. 3). The name "tetris" is also derived from the Greek word tetra meaning four. Electronika 60 had no support for graphic elements so tetriminos were created by using alphanumeric characters on a green/black screen (Gerasimov 2018).

Tetris was inspired from a puzzle board game called "pentaminoes." Differently shaped 12 (not counting mirror shapes) puzzle pieces were created by the combining five (penta) equal squares and the aim of the game was to cover an 8×8 (or more) square units board by using pentaminoes without leaving empty squares.

The game objective of tetris is to manipulate the sequentially falling tetriminos by rotating or moving to left and right sides of the game field (matrix) by using keyboard to fill the bottom squares of the matrix without any gaps. Every filled line of squares is deleted from the game field and stacked lines fall down to fill the empty lines.

Tetris was ported to personal computers very quickly by Gerasimov (Gerasimov 2018, Fig. 4). The versions in Electronika 60 and PC's had almost the same interface, and a keyboard to play. Although the graphic assets are more detailed and appealing and the designers added more features to he game for PC versions, the game experience is almost the same for PC ports of Tetris. Original versions use arrow keys and index, middle and ring fingers for controlling tetriminos favouring the right handed players.



Redesigning Games for New Interfaces and Platforms, Fig. 3 Tetriminos. (Image created by the author)

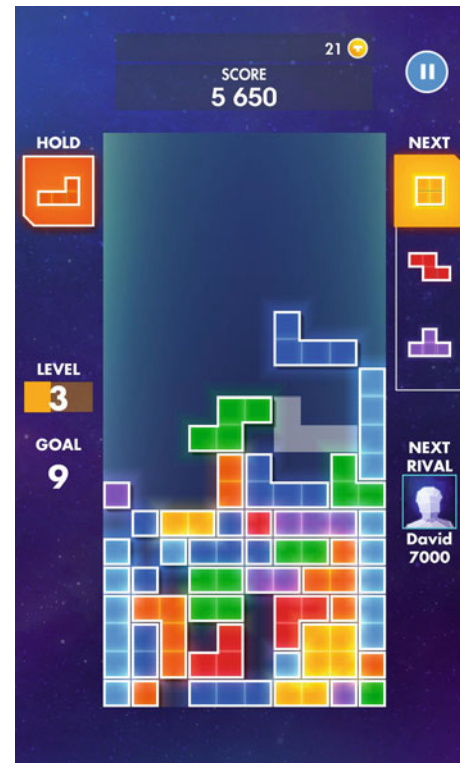
Redesigning Games for New Interfaces and Platforms, Fig. 5 Several dedicated handheld consoles which runs Tetris clones. (Image created by the author)

Tetris became very popular and the game's penetration rate was so high that special tetris consoles (with different names and slightly different shaped tetriminos) were produced. Because of the geometry and size of these consoles, users must hold these machines with two hands while using left hand thumb finger to move and right hand thumb finger to rotate pieces – a design which creates slightly different game experience and control precision (Fig. 5).

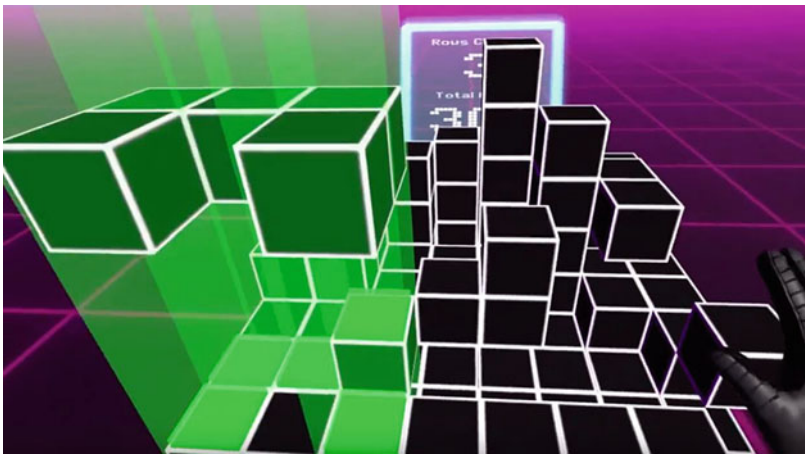
After more than 20 years of its first release, when smart phones become popular in first decade of 2000s, several tetris ports which can run on smart phones were introduced to the market. Since the common types of smart phones use touch screens, taps, and swipe gestures, most ports of tetris to mobile platforms also use taps on touchscreen to mimic buttons of the keyboard. Tapping on the screen has a very different feeling and a lack of feedback compared to pressing a real button. This, typically, changes the gaming experience negatively. So some ports of tetris for smart phones were dramatically redesigned while keeping the simple game mechanics while adding a lot more gaming and controlling features (e.g., refining swipes to move pieces with tapping at any place on screen instead of a virtual button) consistent with the dynamics of screen wipes and tapping (TouchArcade 2008; Electronic Arts 2011; Cassidy 2017). These were some examples to cover the subject adapting the same game to different platforms (Fig. 6).



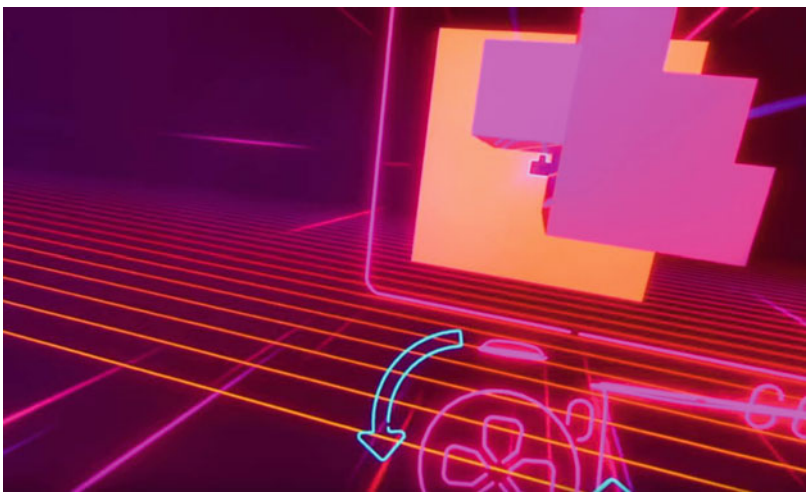
Redesigning Games for New Interfaces and Platforms, Fig. 6 Electronic Arts Tetris version for mobile platform. (Image captured by the author)

There are also other examples of redesigning a tetris like game while being inspired by the original game. The original tetris is a two-dimensional game, and it mimics the falling pieces viewed from the side-view by the player. When it is time to port this two-dimensional game to an immersive environment, two-dimensional nature of tetris is not enough for the features and potential of the VR environment. On one hand, creating a tetris game using three-dimensional pieces with same game mechanics and rules can techically run on a VR hardware. However, on the other hand, VR environment is a 360-° environment and by using special sensors, players can walk around and observe any three-dimensional object from all angles. Compared with the keyboard keys, handheld triggers and button sets are not very precise and ergonomic for the precision needs of tetris. That's why, in this case simply porting the same game to VR environment is almost nonplayable.

BlockWave (RLTYCHK 2016) and Super Hyper Cube (Kokoromi 2016) are two examples of redesigned games influenced by from tetris. Compared to Super Hyper Cube (Fig. 8), BlockWave (Fig. 7) is a game more similar to the original tetris, and it looks like the two-dimensional game area was replaced with a three-dimensional volumetric game space. Supporting this decision, tetrinos are created as three-dimensional pieces and moving and rotation of pieces are made possible by touching the virtual



Redesigning Games for New Interfaces and Platforms, Fig. 7 A screen shot during game play from Block Wave VR (2016). (Image captured by the author)



Redesigning Games for New Interfaces and Platforms, Fig. 8 A screen shot during game play from Super Hyper Cube (2016). (Image captured by the author)

objects through hand controllers. Super Hyper Cube on the other hand uses pieces looking like tetrinos, but they have more variations and can change geometry in time. Some game mechanics were also borrowed from tetris (e.g., placing the correct piece geometry into a gap in an incoming obstacle coming through the camera to destroy the obstacle and make camera continue to move forward).

Conclusion

Here it was defined five levels in game redesign processes of games in three main zones that were ported to another platform. Shortly, first group was adapting the same game to another platform. This group has two levels in relation with the fidelity of the ported game to the original game by means of game elements and interfaces. These were porting to a similar platform and porting to a different platform. Porting a game to a similar platform usually has no critical effect on game dynamics and experience. Porting to a different platform, due to the inconsistencies in interface technologies of the original and the new platforms, can have some serious effects on game dynamics and can force designers to redesign main game elements to keep the game playable. Second zone, third level, is nonplayable zone. A game falls in this zone when the inconsistencies between the interfaces of the original and the new platforms are so serious so that even though the game can run on the new platform technically, players can not play or not prefer to play the game. Last zone is the redesign zone consists of two levels. These are: inspire from the original game and design a similar game, or inspire from the original game and design a new game. A similar game is not the same game running on the new platform, but still resembles the original game with serious changes in main game elements to meet the needs and features of the new platform. At this level, changes in narrative and genre can be seen frequently in the ported game. Last level is designing a new game inspired by the original game. At this level, the new game hardly resembles the original game but traces of the original game can be still recognizable by the player.

In the future, new game consoles and technologies will be developed. Any new computing technology will exist with its unique interface technology. Games will also be adapted and ported in crossplatforms in the future. As long as the distance between the original interface and new interface is large enough to be located beyond the nonplayable zone, game designers will create redesigns to make their games playable. Redesigning can be a good way to keep games up-to-date and even create new games inspired by the original game.

Redirected Walking

► Spatial Perception in Virtual Environments

Redirected Walking in Virtual Reality

Eike Langbehn and Frank Steinicke
Human-Computer Interaction, Universität Hamburg, Hamburg, Germany

Synonyms

Redirection techniques

Definitions

Redirected Walking (RDW) is a collection of virtual reality (VR) locomotion techniques for immersive virtual environments (IVE) that enables humans to walk on paths in the real world, which may vary from the paths they perceive in the virtual environment (VE). RDW can be implemented by manipulations applied to the displayed scene, usually by using redirection gains, which force the user to compensate by repositioning and/or reorienting themselves in order to maintain their intended walking direction in the VE. Within certain detection thresholds, such manipulations cannot be noticed by the user.

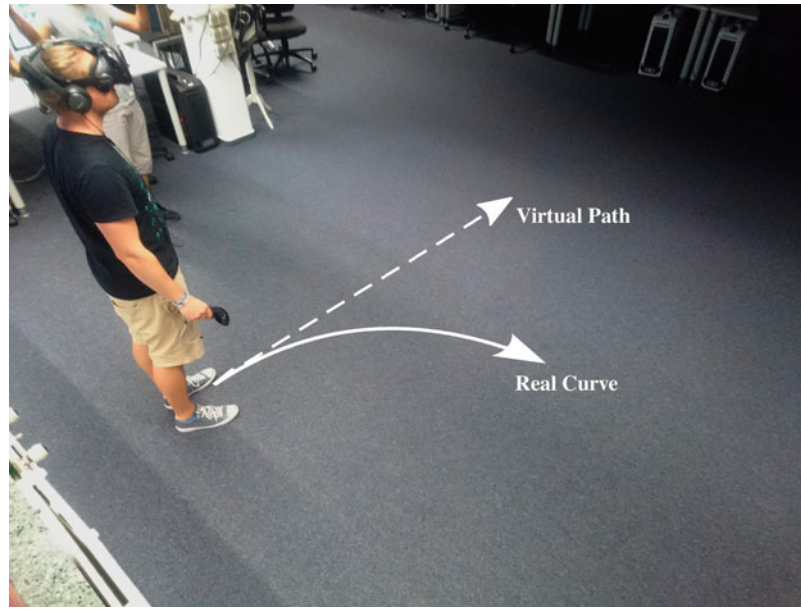
Introduction

Locomotion is one of the most important forms of interaction in VR, but its realistic implementation is also one of the most challenging task in VR development (Steinicke et al. 2013). Real human walking is the most natural way of locomotion in VR (Steinicke et al. 2013) due to its multimodal nature. Furthermore, real walking is beneficial regarding the increased sense of feeling presence (Usoh et al. 1999), improved spatial knowledge (Peck et al. 2011; Ruddle and Lessels 2009; Ruddle et al. 2010), or reduced VR sickness symptoms (LaViola Jr 2000). When using real walking, unfortunately the size of the VE is limited to the size of the tracking space in the physical world. Therefore, a lot of alternative locomotion techniques have been developed, for example, virtual travel techniques such as teleportation (Bozgeyikli et al. 2016) or flying (Usoh et al. 1999), hardware devices like omnidirectional treadmills or motion platforms (Bouguila and Sato 2002; Iwata et al. 2006; Schwaiger et al. 2007), and walking-in-place (Langbehn et al. 2015; Nilsson et al. 2016a). An interesting collection of techniques are Redirection Techniques because they promise to combine the advantages of real walking with the exploration of unlimited VEs. This entry provides an overview of different redirection techniques, including steering algorithms, resetting techniques, and detection thresholds.

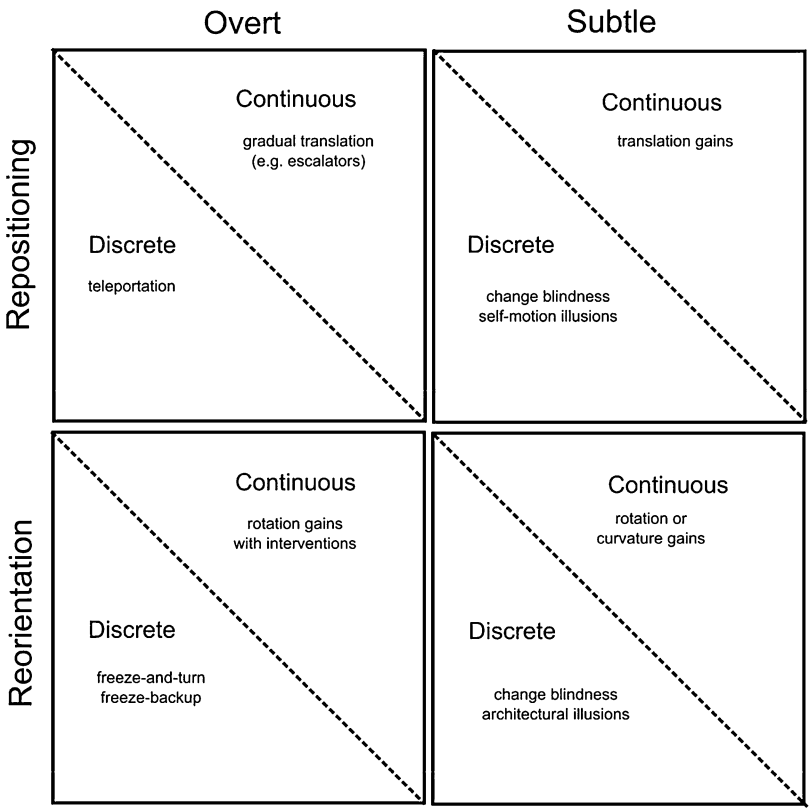
Redirection Techniques

The traditional approach of Redirected Walking that was introduced by Razzaque et al. (2001) is based on slightly rotating the user's view to one direction while she walks on a straight path in the VE. Then, she will unconsciously compensate the rotation by walking on a curved path in the opposite direction. As a result, she will walk on a circular arc in the real world (cf. Fig. 1). About a decade later, Steinicke et al. revisited this technique and described this and other manipulations by means of gains. For example, curvature gains can be defined as follows: $g_C := \frac{1}{r_{real}}$ where r_{real} describes the radius of the circle on which the users are guided in the real world (Steinicke et al. 2010). When redirecting a user, her visual feedback is consistent with movements in the VE, but proprioceptive and vestibular feedback systems are coupled to the physical world. It is known from perceptual and cognitive psychology that vision often dominates proprioception and vestibular sensation when the information from these senses is in conflict (Berthoz 2000; Dichgans and Brandt 1978). However, if the visual-proprioceptive conflicts are small enough, humans will not even be able to notice that they are manipulated. In perceptual experiments where human participants can use only vision to judge their motion through a virtual scene, they can successfully estimate their momentary direction of locomotion, but are worse in perceiving their paths of travel (Bertin et al. 2000; Lappe et al. 1999). Since humans tend to compensate for slight visual-proprioceptive inconsistencies during locomotor control while walking, it becomes possible to guide users along real-world paths, which differ from the paths they perceive in the virtual world.

There are several other redirection techniques in addition to curvature gains. While the traditional RDW approach is based on curvature gains, the terms Redirected Walking and Redirection Techniques are often used almost interchangeably. Suma et al. introduced a taxonomy of Redirection Techniques (cf. Fig. 2) that classifies these techniques into the categories Repositioning or Reorientation, Subtle or Overt, and Discrete or Continuous (Suma et al. 2012a). Repositioning techniques manipulate the position of the virtual viewpoint of the user, whereas reorientation techniques manipulate their orientation, which are usually focused on the yaw rotation. Subtle techniques are intended to be not noticed by the user, that is, manipulations are below the user's detection thresholds.



Redirected Walking in Virtual Reality, Fig. 1 A user walking virtually straight while being redirected using a curvature gain



Redirected Walking in Virtual Reality, Fig. 2 Taxonomy of redirection techniques. (Adapted from Suma et al. 2012a)

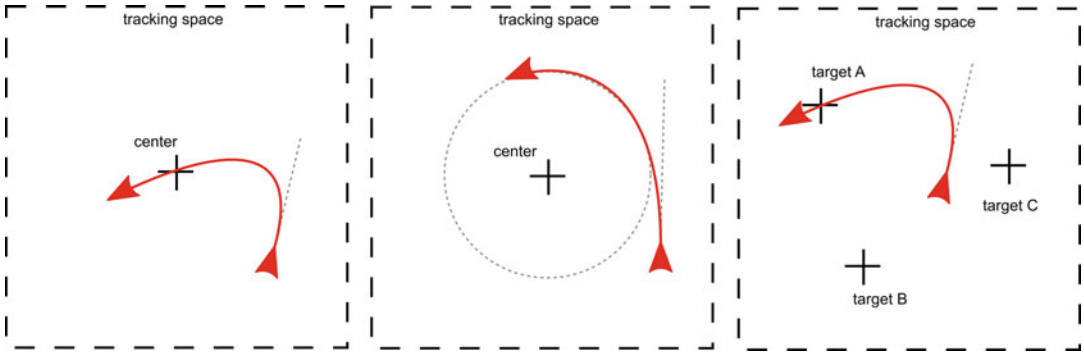
Discrete techniques redirect the user in discrete steps. For example, instant teleportation (Bozgeyikli et al. 2016) is a discrete overt repositioning technique, and impossible spaces (Suma et al. 2012b) are a discrete subtle redirection technique based on scene layouts, which would be impossible in the real world. For instance, such impossible spaces are composed of scenes whose architecture is self-overlapping or changing when the user does not pay attention. Continuous techniques, on the other hand, make use of a continuous motion. One set of techniques in this category are gains for translation, rotation, and also curvature. A gain describes differences between real and virtual motions, that is, ratios between a user's movements in the real world and in the VE. A translation gain $g_T = \frac{T_{virtual}}{T_{real}}$ manipulates the virtual velocity of the user, making her walk slower or faster in the VE compared to the velocity in the real world (Interrante et al. 2007). A rotation gain $g_R := \frac{R_{virtual}}{R_{real}}$ increases or decreases the virtual rotation of the viewpoint relative to the rotation in the real world.

However, no matter which technique is used, when the user hits a boundary of the tracking space, she has to be stopped and reset in a suitable way. For this resetting phase, several discrete and continuous approaches exist, for example, freeze-and-turn (Williams et al. 2007) or visual distractors (Peck et al. 2008).

Steering Algorithms

When implementing RDW with curvature gains, two things have to be provided or assumed: (i) the target of the user in the VE and (ii) the target of the redirection in the real world. Then, the amount of redirection, that is, the gain, can be calculated and a corresponding rotation can be applied to the user's view.

The target of the user can be predicted by using the current gaze direction, which is available



Redirected Walking in Virtual Reality, Fig. 3 Steering algorithms: Steer-to-center, steer-to-orbit, and steer-to-multiple-targets. (Adapted from Razzaque 2005)

through rotational head tracking (Steinicke et al. 2008c) or eye tracking (Zank and Kunz 2016), the past walking direction (Zank and Kunz 2015), or the direction of the user's torso. A combination of these methods or the usage of probabilistic models is also possible (Schrempf et al. 2007).

In small tracking spaces, it is required to steer the user away from the boundaries. Therefore, Razzaque proposed three algorithms: (i) steer-to-center, (ii) steer-to-orbit, and (iii) steer-to-multiple-targets (Razzaque 2005). These techniques are based on the idea to redirect the user always to a certain point, on a certain orbit, or to multiple certain points (cf. Fig. 3), that is, these are the targets of the redirection in the real world. In these scenarios, the user's walking direction is constantly changing while she is walking freely in the virtual world. Hence, the required amount of redirection is constantly recalculated so that the user is always steered towards these certain points or orbits. Hodgson et al. (Hodgson and Bachmann 2013) added the (iv) steer-to-multiple-centers algorithm, which is an extension of the steer-to-multiple-targets algorithm, and compared them regarding metrics like number of wall contacts and maximum distances from the tracking area center. In these experiments, steer-to-center showed the best performance. In another experiment, where the VE was constrained by virtual walls and the walking directions were therefore limited, steer-to-orbit performed better (Hodgson et al. 2014). In general, larger tracking spaces offer improved performance starting with a minimum viable size of approximately 6×6 m (Azmandian et al. 2015). Instead of using the center or random targets, it might be beneficial to use physical proxy objects inside the tracking space as steering targets (Steinicke et al. 2008c). These objects can provide the user with passive haptic feedback for unlimited virtual objects (Kohli et al. 2005). Hodgson et al. (2011) introduced a generalized RDW algorithm for gymnasium-sized spaces while others implemented their algorithms for spaces with a size of approximately 6×6 m (Suma et al. 2015).

In order to guide users always in an optimal way, a planning method can be used to select the most suitable redirection technique for a given situation (Zmuda et al. 2013). Therefore, a manually defined graph of weighted walking paths based on the known VE is used to predict the user's travel path. This technique revealed a significant improvement compared to the steer-to-center algorithm (Nescher et al. 2014). Furthermore, it has been shown that the graphs can be generated automatically based on navigation meshes (Azmandian et al. 2016b; Zank and Kunz 2017). Another method is to map virtual and physical reality in such a way that only a minimal redirection is necessary (Sun et al. 2016; Nitzsche et al. 2004).

There were also approaches, which combined RDW algorithms with other travel techniques such as portals (Bruder et al. 2009; Steinicke et al. 2009; Freitag et al. 2014) or redirection-free zones (Lubos et al. 2014). Recently, a method of RDW

Redirected Walking in Virtual Reality, Fig. 4 Illustration of the RDW approach based on virtual curves: (a) a virtual pathway in the VE constructed of several curves and intersections with (b) the corresponding real-world walking configuration consisting of several curve segments in the laboratory. The presented application requires approximately a tracked real-word space of about 4 m × 4 m, whereas the VE presents approximately a 25 m × 25 m large model

has been introduced, which constraints walking in the VE to curved paths (Langbehn et al. 2017b). For this, several curves are fitted into the tracking space and connected at specific intersections at which the user can change her walking direction. This way the boundaries of the tracking space are never hit as long as the user stays on the predefined paths in the VE (cf. Fig. 4).

Resetting Phase

No matter which redirection technique or steering algorithm is used, it can still hap-pen that the user hits a boundary of the tracking space. In this case, she needs to be stopped and reset, that is, the user must be turned to face to the center of the tracking space again. For instance, most redirection solutions, for example, the RDW toolkit (Az-mandian et al. 2016a), make use of a stop-and-go approach. Using these approaches, the user walks until the boundary of the tracking space is reached, for example, while a curvature gain is applied. Then, she will be rotated until there are no obstacles in front of her new walking direction. Afterwards, the user can continue walking in the desired direction.

For this resetting phase or reorientation phase, several techniques exist. Williams et al. introduced the three methods (i) Freeze-Backup, (ii) Freeze-Turn, and (iii) 2:1-Turn (Williams et al. 2007). In the Freeze-Backup method, the position of the user in the VE is frozen and she can walk backward until she has enough empty physical space in front of her. In the Freeze-Turn method, the orientation of the user in the VE is frozen and she can turn around until she has enough empty physical space in front of her. In the 2:1-Turn method, the user turns around 180 degrees physically (so that she has enough empty physical space in front of her), while she turns 360 degrees virtually (and looks in the same direction in the VE as before the turn). Such a manipulated turn is implemented using a rotation gain $g_R = 2$. In this case, visual distractors can be used to make these manipulated turns less obvious and to appear more natural (Peck et al. 2008, 2011). The resetting phase can also be integrated into the domain of the VR application by using suitable metaphors, for example, a turning bookshelf (Yu et al. 2017).

To reduce the number of resetting phases in this stop-and-go approach, Zhang et al.

Redirected Walking in Virtual Reality, Table 1 Detection Thresholds of Redirection Techniques

Gain	Comment	Thresholds[a]	=°/m Notation[b]	Source
Translation	Question Bias	0.78–1.22	–	(Steinicke et al. 2008a)
Translation	–	0.78–1.22	–	(Steinicke et al. 2010)
Translation	–	0.87–1.29	–	(Bruder et al. 2012)
Translation	Driving	0.94–1.36	–	(Bruder et al. 2012)
Translation	–	0.86–1.26	–	(Kruse et al. 2018)
Translation	Virtual Feet	0.88–1.15	–	(Kruse et al. 2018)
Translation	Low-cue VE	0.73–1.25	–	(Kruse et al. 2018)
Rotation	Question Bias	0.59–1.1	–	(Steinicke et al. 2008a)
Rotation	–	0.67–1.24	–	(Steinicke et al. 2010)
Rotation	–	0.68–1.26	–	(Bruder et al. 2012)
Rotation	Driving	0.77–1.26	–	(Bruder et al. 2012)
Rotation	–	0.93–1.27	–	(Paludan et al. 2016)
Rotation	16 objects	0.82–1.20	–	(Paludan et al. 2016)
Curvature	Question Bias	$r > 16$ m	3.5 = °/m	(Steinicke et al. 2008a)
Curvature	Question Bias	$r > 24$ m	2.35 = °/m	(Steinicke et al. 2008a)
	& 2 m start-up	$r > 22.03$ m	2.6 = °/m	
Curvature	–			(Steinicke et al. 2010)
Curvature	–	$r > 14.92$ m	3.84 = °/m	(Bruder et al. 2012)
Curvature	Driving	$r > 8.97$ m	6.39 = °/m	(Bruder et al. 2012)
Curvature	$v = 0.75$ m/s	$r > 10.57$ m	5.42 = °/m	(Neth et al. 2012)
Curvature	$v = 1.00$ m/s	$r > 23.75$ m	2.41 = °/m	(Neth et al. 2012)
Curvature	$v = 1.25$ m/s	$r > 26.99$ m	2.12 = °/m	(Neth et al. 2012)
Curvature	–	$r > 11.61$ m	4.9 = °/m	(Grechkin et al. 2016)
Curvature	Audio	$r > 27.5$ m	2.08 = °/m	(Serafin et al. 2013)
Curvature	Audio & Vision	$r > 6.0$ m	9.55 = °/m	(Meyer et al. 2016)
Bending	$r_{real} = 1.25$ m	3.25	31.7 = °/m	(Langbehn et al. 2017a)
Bending	$r_{real} = 2.5$ m	4.35	17.6 = °/m	(Langbehn et al. 2017a)

[a]For translation and rotation gains, the range of undetectable gains is stated. For bending gains, the maximal gain is stated. For curvature gains, the radius of the resulting arc in the real world is stated

[b]For comparing curvature and bending gains, this notation is more suitable since it does not rely on the radius of the curves. It can be calculated if real and virtual radii are given

(Zhang and Kuhl 2013; Zhang et al. 2015) developed heuristics to dynamically adjust RDW gains for guiding the user in the best direction. It turned out that the users walked a significantly longer distance between two resetting phases when using this method.

Detection Thresholds

Redirection techniques may be subtle under certain conditions. Therefore, detection thresholds for different manipulations have been analyzed. We collected several estimated detection thresholds for different gains and conditions in Table 1.

Steinicke et al. conducted several experiments to reveal detection thresholds for translation, rotation, and curvature gains (Steinicke et al. 2010). The detection thresholds indicate just-noticeable differences between vision and proprioception. In order to determine these thresholds, a two-alternative forced-choice (2AFC) task was used. This means, for example, for path curvature, users walked a straight path in the VE, which was bent by a curvature gain either to the left or to the right

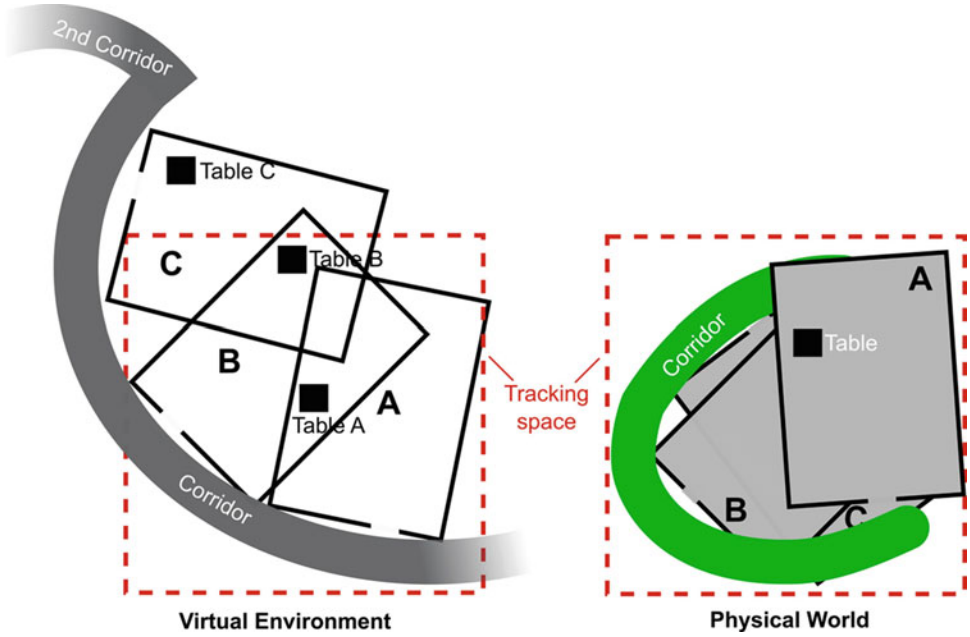
in the real world. Then, they had to judge if the physical path was bent left or right. The pooled data of this task can be used to generate a psychometric function that determines the detection thresholds. While there most likely was a bias in the question of their first experiments (Steinicke et al. 2008a), they repeated them (Steinicke et al. 2010). Accordingly, a straight path in the VE can be turned into a circular arc in the real world with a radius of at least 22 m, for which users are not able to consciously detect manipulations. This means that a physical space of at least 45 × 45 m would be necessary to enable infinite virtually straight walking. Furthermore, rotations can be scaled by gains between 0.67 and 1.24 and translations can be scaled by gains between 0.78 and 1.22 without that users are able to detect the manipulations.

These experiments have been replicated and extended several times (Steinicke et al. 2008b, 2009; Bruder et al. 2012). It was shown that rotation manipulations are less obvious to detect if the VE moves against head rotation than if the VE moves with head rotation (Jerald et al. 2008). It was found that sensitivity to curvature gains depends on walking velocity: a slower walking speed allows higher redirection gains (Neth et al. 2011, 2012). Redirection can also be applied for driving simulations, for example, when applying curvature gains to a user sitting in an electric wheelchair, this resulted in greater possible redirection (Bruder et al. 2012), which might be related to the proprioceptive feedback users receive by walking, whereas this feedback is mostly missing while driving in a wheelchair. When combining curvature gains and translation gains, curvature detection thresholds are not affected (Grechkin et al. 2016). So far, curvature detection thresholds were estimated when the users walk straight ahead in the VE. Recently, the concept of curvature gains has been extended to so-called bending gains $g_B := r_{virtual} \times g_C = \frac{r_{virtual}}{r_{real}}$, which define how much a physical path can be bent for situations in which users do not walk straightforward, but walk on a virtual curve in the VE (Langbehn et al. 2017a). An effect of the visual density of the VE, that is, the number of visual objects that were present in the VE, on the detection thresholds could not be shown (Paludan et al. 2016). However, the visual fidelity of the VE is more important than the visualization of the user's feet (Kruse et al. 2018). Subtle redirection techniques may not only be based on visual manipulations of the VE, but also on audio (Meyer et al. 2016; Nilsson et al. 2016b; Nogalski and Fohl 2016) or haptics (Matsumoto et al. 2016b). When using passive haptic cues during RDW even more redirection is possible (Matsumoto et al. 2016a). Of course, detection thresholds may be individually different for different users (Thi Anh Ngoc et al. 2016).

Although, ideally RDW is a subconscious process, Bruder et al. have shown that cognitive resources are required to compensate even subtle manipulations (Bruder et al. 2015). In secondary verbal and spatial memory tasks, they have shown that performance decreased in the secondary task when the redirection gain increased. More precisely, correct answers decreased and answer time increased as well.

Redirected Spaces

An alternative approach to implement RDW is to use impossible or flexible spaces (Va-sylevska et al. Vasylevska et al. 2013), which can be based on self-overlapping or changing architectural layouts. In these spaces, the VE itself is manipulated (in contrast to the user's viewpoint) with the same goal of enlarging the virtual space, which can be explored by real walking. Such manipulations can be realized, for example, by moving walls or doors outside the user's view (Suma et al. 2010) to exploit the same real-world space for different virtual rooms. The phenomenon that users are unable to detect such changes is known as change blindness (Simons and Levin 1997). It was shown that virtual rooms may overlap by more than 50% before users detect the manipulation (Suma et al. 2012b). Moreover, curved corridors between the overlapping rooms are more beneficial than right-angled corridors in



Redirected Walking in Virtual Reality, Fig. 5 An illustration of the combination of redirected walking and impossible spaces. The virtual environment consists of a curved corridor and rooms A, B, and C. The corridor and the rooms are larger than the available tracking space although the rooms overlap already (left). When applying a redirection gain at the corridor the VE is compressed even more and the whole setup fits into the tracking space (right). There the virtual tables are merged into one physical table. This design can be repeated with another corridor that is connected to the first one

terms of manipulation detection (Vasylevska and Kaufmann 2017), and a corridor with additional turns is more efficient than a longer corridor (Vasylevska and Kaufmann 2015).

Impossible spaces can be combined with curvature-based RDW (Langbehn et al. 2018) to leverage a small tracking space optimally (cf. Fig. 5). In particular, the use of curved corridors benefits both methods (Vasylevska and Kaufmann 2017; Langbehn et al. 2017a).

Conclusion

Although a lot of research results were collected since RDW was first introduced, there is still no standard solution for unlimited walking in a restricted tracking space without interruptions. However, the existing techniques can already be used for different applications, for example, games (Steinicke et al. 2009) or architecture (Bruder et al. 2009). For future work, there are challenges in all areas of RDW. Steering algorithms and path prediction methods might be improved using machine learning algorithms. Procedural generation of virtual worlds might simplify the use of impossible spaces. Furthermore, detection thresholds might be investigated regarding their usability, since even perceivable gains might be acceptable by users. It is also not known if users adapt to redirection and if it might be possible to increase a gain after a certain while in the VE. Moreover, there is little work on RDW in multiuser environments so far (Azmandian et al. 2017).

To summarize, redirected walking is a fascinating field of VR, which combines the fields of human-computer interaction, computer science, and psychology allowing users to explore a VE in the most natural way, that is, by real walking.

Exergames

Definitions

Rehabilitation games are a subset of serious games intended to promote increased musculoskeletal or neural activity with the aim of therapeutic benefit in the patients or players of these games. This encyclopedia entry is in a digital context.

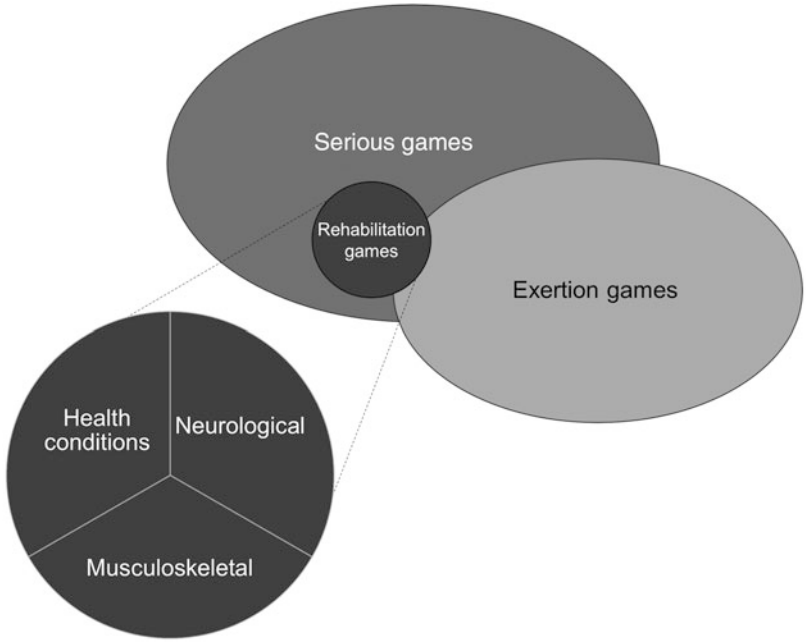
Introduction

Serious games, often called games for learning, are games intentionally created for more than mere entertainment (Abt 1970), and in the advent of digitalization, the term digital games based learning (DGBL) has enjoyed widespread synonymic acceptance. DGBL, as the name suggests, encompasses all digital games that are created with intent to facilitate learning – be it to acquire knowledge, change behavior, or improve motor and neuro functioning. Another such term that gained popularity, largely due to console platforms such as Nintendo Wii and Xbox Kinect (and their respective game releases), is exertion games (exergames). Although exergames are generally directed at physical exertion that goes beyond couch-bound gameplay (Oh and Yang 2010), when the aim of exergaming becomes an attempt at changing habitually sedentary behavior into active behavior, an overlap with serious games emerges.

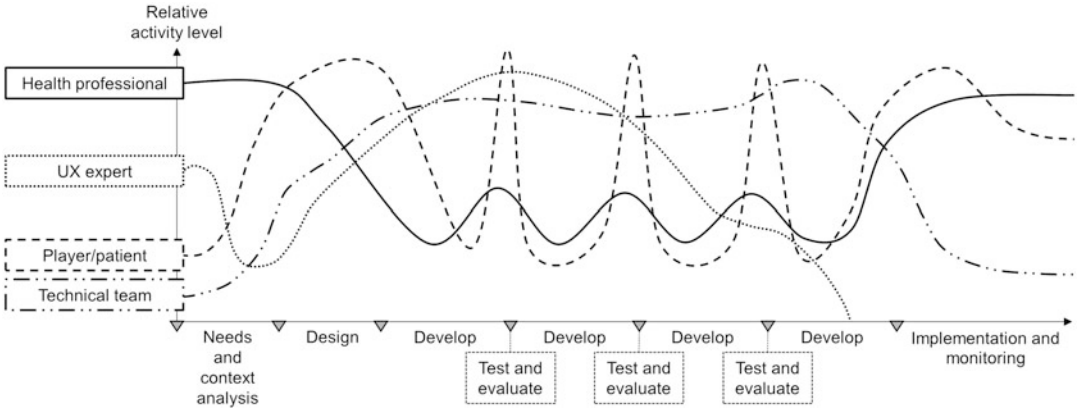
Rehabilitation games, on the other hand, are considerably more directed and have found a niche application as tools for therapeutic recovery or rehabilitation from a host of health related matters (Fig. 1). That is, rehabilitation games are set upon players learning to improve or regain motor and neuro functioning (Rego et al. 2010), positioning such games squarely as a subset of serious games (Fig. 1). Furthermore, rehabilitation games can address, by means of improved cardiovascular fitness, physiological health conditions such as acute hypertension, raised blood sugar, or heightened cholesterol. Since improved cardiovascular fitness falls in the exergaming realm, an intersection between exergames and rehabilitation games becomes apparent (Fig. 1).

Where the success of serious games is continuously challenged with striking an equilibrium between pedagogy and fun, rehabilitation games add control accuracy as a third aspect to this precarious balancing act. It is not enough to merely add an appealing layer of engagement to a set of prescribed exercises. Even if this engagement follows all the guidelines for successful serious games, there exists a real risk that players could injure themselves if their movements are not conducted with strict form (Saini et al. 2012). Additionally, rehabilitation games are typically destined for those who are likely to be (out of fear for re-incurring their injury) reluctant to play, making that the user experience becomes ever more important in overcoming the challenged internal motivation to engage with such games.

Rehabilitation games are primarily in place to encourage a persistent engagement with activities until complete rehabilitation has taken place. In other words, rehabilitation games must motivate. All this makes for a significantly complex kaleidoscope of factors and role players to be considered when designing, developing, and implementing rehabilitation games.



Rehabilitation Games, Fig. 1 Primary application categories of rehabilitation games and positioning of rehabilitation games within the serious and exertion games space



Rehabilitation Games, Fig. 2 Timeline for rehabilitation game development phases that shows the relative activity levels for each of the key role players

The Development Process

Rehabilitation games are born from the human body's biokinetic and neurological ability to recover from various injuries. Rehabilitation games have human users. In extension, users of rehabilitation games should not be regarded as players but rather as patients with personal agendas, motivations, and practical environments. Neglecting to consult the patients of rehabilitation games from early phase conceptualization through to implementation (Fig. 2) is bound to result in poorly construed games that will find a dusty shelf rather than active interaction with the patient. The strong patient presence during the design phase (Fig. 2) reverberates the general notion that a serious game's target audience should be valued as co-designers (Ravyse et al. 2017), rather than users only for testing.

Representing users of rehabilitation games as patients implies that a health professional forms part of the recovery process and hence also the

game development process. These health professionals have a dichotomous role of conveying the therapeutic requirements of the exercise in question and evaluating the level of control that the game exacts on patient engagement (Pirovano et al. 2016). That is, ensuring that the game does not cause additional or renewed injury to the patient. In conveying exercise protocol to the game designers, health professionals indirectly also act as hardware consultants, in that a clearly defined protocol will make it apparent whether custom controllers are required or if standard game input devices will be sufficient for effective and relatively risk-free rehabilitation. Furthermore, unless artificial intelligence (AI) can be developed and trusted to such an extent that it is capable of leading patients through the different rehabilitation phases, health professionals must be at hand to provide both real-time and delayed feedback on the progress of patient rehabilitation – be it remotely or in person. Health professionals therefore play their roles during very distinct phases of development (Fig. 2), namely: (a) early design, where they convey the exercise requirements and advise on controller selection; (b) user testing, where they ensure the integrity of the therapy in question; and (c) implementation, where they guide patient progress.

With the emphasis on therapeutic accuracy, rehabilitation games often tend to relegate usability and (more so) user experience (UX) to triviality (Pirovano et al. 2016). In order to avoid the situation of an uninspiring – albeit remedially precise – rehabilitation game, enlisting the service of a UX expert should not be overlooked. Their part-to-play commences early in the context analysis phase with an ethnography study of the user. From here, the UX expert's level of activity decreases rapidly until the period preceding the first user tests, where their involvement peaks. Thereafter, UX expert participation gradually tapers down until diminishing entirely just prior to implementation (Fig. 2).

This leaves the technical team (game designer, programmers, visual and sound artists) to bring the rehabilitation requirements to life while keeping with a maximal UX. The technical team, with varying degrees of content-demand individual workloads, will be active from the very beginning of the project and well into the implementation phase where they will have rehabilitation game maintenance responsibilities (Fig. 2).

Usability and User Experience (UX)

Usability and UX are composed of an interplay between the three core elements of a rehabilitation game environment – the technical (or game) element, the patient (or player) element, and the professional therapy (or rehabilitation) element. It is up to the UX designer to ensure that the patient's attitudes and emotions about their therapy are attended to in a game that: (a) appropriately matches gameplay to the therapy context, and (b) caters to the patient's gameplay preferences and exercise habits. Consequently, in order to improve the game from the player's point of view, UX design and evaluation is interested in player perceptions and responses during and after play sessions. UX in games is described and measured through concepts such as immersion, engagement, presence, fun, and flow (Bernhaupt 2015). Successful UX design increases the attractiveness of rehabilitation games for potential users and maintains the motivation of current players.

Since rehabilitation games are purposed beyond the game context, usability is another fruitful design concept that ensures the hedonic aspects of the gaming experience do not overrule important rehabilitation design elements. Usability is concerned with the extent to which a user can use a system with effectiveness, efficiency, and satisfaction (ISO 1998). Where UX design is sensitive to patient health and well-being while continuously reinforcing a sense of achievement through an aesthetically pleasing game interface, usability highlights the more pragmatic aspects of rehabilitation games as a goal-oriented activity. For instance, usability addresses rehabilitation game relevant questions about controller suitability and feedback clarity from a patient perspective. Such usability measures can be used for assessing player understanding and interaction with the primary control mechanic (target rehabilitation movement) as well as their perceived

usefulness of the rehabilitation game. Negative controller experiences and misconstrued user interface communication will certainly cause patients to abandon continued use of rehabilitation games (Ravyse et al. 2017).

Common methods to collect user experiences and usability data throughout the rehabilitation game development cycle include playtests, live observations, interviews, questionnaires, and video and data logging. The route to positive UX begins by defining goals, desires, and target groups and continues with an iterative user-centered design (UCD) life cycle. Methods include focus groups, individual interviews, and personas. Persona descriptions attempt to clarify user preferences for free-form or instructed rehabilitation sessions, regular or periodical training intervals, self- or social competition, fictional or realistic game designs, and so forth. Despite the common goal to rehabilitate, personal goals may vary. Rehabilitation game designs should therefore implement features and settings that can be personalized (to some extent) before and during the different phases of the game's rehabilitation journey.

Application Areas

Rehabilitation takes place when the biomechanical, physiological, or neurological functioning of the human body is being restored to a former more functional state (Prentice and Kaminski 2004). Due to largely speculative evidence supporting game-based neurological forming and the limited success of games promoting participation in physical activity in pursuit of sound physiological functioning, the leading pragmatic use of rehabilitation games is to recover motor skills. Furthermore, rehabilitation games have a distinct operational phase within this physical rehabilitation process.

The pathway to biomechanical recovery either stems from surgery, diagnosis of disease affecting motor ability, or trauma resulting in injury. The latter may also require corrective surgery, complicating the recuperation pathway somewhat. No matter how complex the pathway, rehabilitation can be divided into phases with pain and phases that are relatively pain-free. The phases with pain are those immediately following the injury or trauma. The somewhat later, pain-free phases of rehabilitation, usually commence once range of motion has been re-established and is concerned with: firstly, depending on the body part to be rehabilitated, restoring proprioception and, secondly, reinstating strength and flexibility (Prentice and Kaminski 2004). Although academic experimentation with games that assist in giving back range of motion (i.e., in the phase with pain) are not uncommon, it is understandable that the larger corpus of rehabilitation games is confined to the seemingly lower risk pain-free phases. That is, the most widespread rehabilitation games are for proprioception, balance, strength, and flexibility. Another factor influencing the skewed spectrum of rehabilitation game application is implementation constraint.

Implementation

Pain-free rehabilitation offers two arenas. Patients can remain (whether by choice or prescription) within a healthcare facility or take their exercise regimes home. Healthcare facility rehabilitation falls under the premise of having a health professional available for corrective or supportive assistance when conducting the prescribed rehabilitation exercises. By extension, rehabilitation games can hence be played at a healthcare facility or at home. However, rehabilitation games at healthcare facilities, outside of academic experimentation, are uncommon. This is largely due to issues arising from physical setup, technical support necessities, and user engagement. The most common rehabilitation games are those involving motor skills and inevitably require motion tracking. With the exception of balance and proprioception games that are principally played on sensor boards, motion tracking involves the use of cameras. Such camera setups require significant space and precise location. Furthermore, the risk of occlusion (obscuring the camera view with a physical presence) makes that the space for motion tracking cannot be shared with other

activities. Although Xbox Kinect offers a relatively low-cost and minimal space requirement solution, the risk of occlusion remains, and behind-the-player-interference is a likely hindrance in active environments such as healthcare facilities. Both of these cause disrupted gameplay, resulting in disjointed user engagement with the game, leaving patients frustrated and generally disgruntled with the healthcare facility. Additionally, technical failure (hardware or software) is unavoidable when implementing a technology-based solution and as with occlusion, disruptive failure will run the same dissatisfied-patient course. To some extent, healthcare facilities could mitigate this through incurring the extra cost of having immediate technical support at hand. Considering the single-player-for-single-exercise designs of rehabilitation games, most healthcare facilities find it difficult to justify physical space and budget investment for motion tracking games.

As a homecare solution, budget (and most likely space too) limitations are even more profound than at healthcare facilities. This leaves home use of rehabilitation games in the hands of mainstream platforms such as Nintendo Wii and Xbox Kinect. There exists some evidence in favor of these platforms as out-of-the-box rehabilitation tools and although a meta-analysis of the Wii Fit series shows that it might have potential as a rehabilitation device, the limited number of randomized control trials suggests that research on this is inconclusive (Tripette et al. 2017). This is largely due to the clinical nature of rehabilitation, where control and form of movement are paramount. Kinect and Wii platforms were never intended for clinical rehabilitation and if pursuing strict movement analysis is critical, the development of custom controller hardware becomes obligatory. This does not mean that hardware such as the Kinect camera or Wii balance board, augmenting these popular platforms, is immediately refutable. Many successful musculoskeletal facilitation efforts couple these controllers to bespoke games that are aimed at late phase rehabilitation or other motor skill quality improvements that do not stem from direct physical trauma (e.g., cerebral palsy and Parkinson's disease) – making the Kinect camera and Wii balance board well suited to rehabilitation gameplay at home (Lange et al. 2009).

Home users of rehabilitation games most often perceive the games as virtual personal exercise professionals, positing some level of trust in their implementation (Lewis and Rosie 2012). As such, the actual game (or software) must essentially mimic the uncompromisable rehabilitation practices of constant patient progress monitoring and adjusting the rehabilitation program accordingly. Rehabilitation games satisfy this need by leveraging user profiling techniques with backend database systems that capture patient gameplay activity (Hocine et al. 2014). The activity is captured and translated into suitable metrics that represent the progress of the patient rehabilitation. The selected metric is heavily dependent on the target rehabilitation area and could include anything from stimuli reaction time to angle of flexion and time spent in target heart rate zone. Whatever the metrics of interest may be, they are customarily shared with the patient's health care professional, either in the form of Excel spreadsheets at the conclusion of an exercise session or a custom real-time dashboard. The healthcare professional then either provides immediate or delayed feedback built on the metrics they receive. Immediate feedback relies on real-time data and a direct communication (usually chat) interface. The captured metrics also serve as input for an artificial intelligence (AI) technique called dynamic difficulty adjustment (DDA). DDA occurs when the game, based on algorithmic understanding of the key performance metrics, automatically increases or decreases the gameplay difficulty level in real time – akin to increasing the lifting weight as the patient becomes stronger. As an extension to DDA, camera-based rehabilitation games can benefit from automatic affect recognition based on body movements (Kleinsmith and Bianchi-Berthouze 2013). While DDA has the overall consignment of maintaining flow in rehabilitation games, body movement monitoring ensures that patients do not falter in their rehabilitation movements and can be used to map body posture to

player emotion – answering the all-important question of motivation.

Conclusion

Rehabilitation games work under experimental conditions, and with widespread adoption of rehabilitation games in the hands of homecare (as opposed to healthcare facilities), the focus should be on making games that do not rely on an overemphasis of control accuracy. Motivating the player (or patient) to set up a home rehabilitation gaming environment may essentially stem from the desire to rehabilitate, but custom controllers will place rehabilitation games out of the home consumer's reach in both price and availability. The game context therefore becomes a key success driver behind pervasive use of rehabilitation games and should distance itself from merely grinding through exercise regimes – a home gym can also do this. Rehabilitation games should thus avoid the fallacy of many serious games and instead be set against the backdrop of an alluring narrative with believable non-player character AI.

Sustained engagement with rehabilitation games goes beyond good game design. An equal amount of merit lies in applying sound usability and UX design principles. The reward for such efforts is an emotionally and physically pleasant game that patients will continue playing, rather than seeking other rehabilitation options, potentially lengthening their play sessions and ultimately improving their rehabilitation results.

Currently, improved rehabilitation is the primary responsibility of rehabilitation game AI. DDA and affect recognition manipulate the game's physical interface by altering the patient's physical interaction intensity. Although these AI techniques support the maintenance of flow theory in games, the intrinsic motivation to persist with rehabilitation activities, however, rests in a different space of the psychological realm. Affect recognition has made some progress towards mapping player posture to emotion but has yet to translate this into suitable game response. Having AI that operates, not only on a physical level but also on a psychological level, will make significant strides toward making rehabilitation games truly become the motivational tools they were intended to be.

Global Illumination	Global interaction between the light sources and the surfaces of environment.
Pixel	Abbreviation of the English term picture element.
Radiative Transport	Area that studies the interaction of radiant energy with matter, on a macroscopic scale.
Transference Equation	Integral-differential equation that describes the interaction of light with the participant medium and, given the appropriate boundary conditions, its interaction with arbitrary surfaces.
Transport Theory	Field that embraces all macroscopic phenomena that result from the interaction of infinitesimal particles with the medium. Macroscopic behavior of photons, neutrons, and gas molecules are all within their scope.

Introduction

The basic and fundamental problem of Computer Graphics is to transform data into image. Digital image is the result of most of the processes involved in computer graphics. A mathematical model to describe an image is a function defined in a two-dimensional surface with values in a color space (Gomes and Velho 2008). In this way, this surface is represented by a matrix *row* × *column*, where the number of rows is the vertical resolution and the number of columns the horizontal resolution of the image. Each array's element is called the pixel of the image. And each pixel stores a color value as information.

In computer graphics, visualization is completed by assigning color information to the objects represented in the image. This process is called color and shading. In the case of three-dimensional scenes, it is natural that one chooses to obtain this information by lighting calculation, since the physiological process of human vision occurs through the interaction of light with

objects. Color is a sensation caused by light and perceived by the eyes. In this way, one only perceives colors where the light arrives (Rogers 1998).

The illumination of a 3*D* scene is the result of global interaction between the light sources and the surfaces of environment. Such interaction is called global illumination, a theme of great interest in the search for techniques that allow to simulate the phenomenology of light through physical concepts with the aim of generating synthetic images. The simulation is physics based to achieve the appearance of a hypothetical scene as real as possible. One of the problems encountered in global lighting techniques lies in its computational complexity, since all on-scene objects can interact with each other through light scattering (Arvo 1993).

Global illumination can be seen as a subarea of Radiative Transport, an area that studies the interaction of radiant energy with matter, on a macroscopic scale (Gomes and Velho 2008; Arvo 1993). The radiative transport theory origin, according to Arvo (1993), is attributed to the astrophysical works of Schuster and Schwarzschild (Schuster 1905; Schwarzschild 1906). Since then, this theory has been applied in many areas, such as computer graphics. It is based on the transference equation, an integral-differential equation that describes the interaction of light with the participant medium and, given the appropriate boundary conditions, its interaction with arbitrary surfaces. In addition, global illumination can also be seen as a branch of the Transport Theory (Byron Bird et al. 1960), a field that embraces all macroscopic phenomena that result from the interaction of infinitesimal particles with the medium. Macroscopic behavior of photons, neutrons, and gas molecules are all within their scope. The central equation of the theory of transport is known as the Boltzmann equation (Arvo 1993).

Fundamentals

Lighting is the study of propagation of light in the environment and its interaction with surfaces. A 3*D* scene is composed of objects that emit, reflect, or transmit light energy. According to physics, this light energy behaves as much as particle beam as a wave. The corpuscular model of light postulates that energy flow along a ray is quantized by moving particles called photons. In contrast, the wave model of light describes the light energy by combining the electric field with the magnetic field (Gomes and Velho 2008).

In most problems of light propagation in computer graphics, the interest lies in the illumination of a hypothetical scenario. In order to obtain an illumination equation, it is necessary to establish a physic-mathematical model of light propagation phenomenon. There are three possible models corresponding to three distinct areas, namely, geometric optics, physical optics, and radiative transport (Gomes and Velho 2008; Arvo 1993).

Geometric optics assume that light propagates straight at a constant velocity and models the interaction of that propagation on the surfaces of separation between two media (assuming that those surfaces are optically perfect). It adequately describes the macroscopic effects of light energy transport, such as linear propagation, reflection, and refraction, but does not take into account the concepts of radiometry that allow quantification and measurement of the quantities involved.

Physical optics extends geometric optics by incorporating modeling with Maxwell's equations. In addition to the classical phenomena, it allows the modeling of other phenomena such as scattering, interference, and diffraction, which occur when the scale of scene geometry is less than the wavelength of transported light.

For global illumination, it is necessary to model visual phenomena, that is, observable phenomena through the vision process or some equipment capable of perceiving luminous frequency and intensity. Radiative transport solves the illumination problem as transport of radiant energy. It essentially combines the theory of geometrical optics with thermodynamics. It is a more suitable model for the purposes of image synthesis.

Particle Model

Macroscopic phenomena modeled by radiative transport take into account the particle model of light. In this way, there is a relation with the

photon transport, an area that deals with the macroscopic statistical behavior of particles (Arvo 1993). This simplified light model captures the spirit of transport theory, whose goal is to determine the distribution of particles in space and time, taking into account their movement and interaction with the environment. Transport theory requires assumptions about the nature of particles. The two most important hypotheses are:

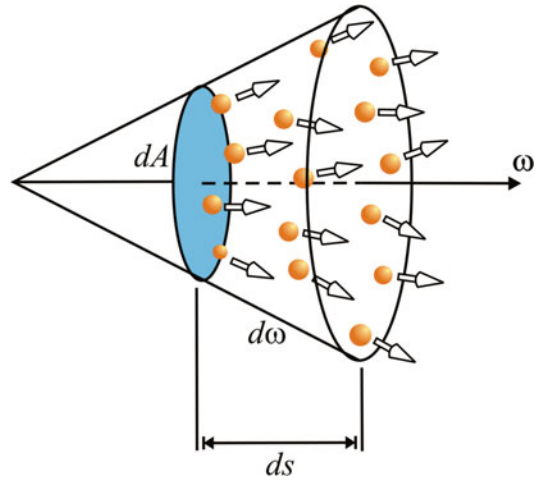
(i) The particles are so small and numerous that their statistical distribution can be treated as continuous.
(ii) At any point in time a particle is completely characterized by its position and velocity and by internal states such as polarization, frequency rate, or spin.

These hypotheses lead to the notion of phase space, an abstraction for dealing with particle configurations. Each dimension of the phase space represents a degree of particle freedom (usually six in total). For the sake of simplicity, the particles are considered to move at a constant speed c and have no internal states. According to Arvo (1993), this simplification corresponds to mono-energy radiative transfer, or mono-velocity transport to generic particles. The hypothesis of velocity requires only five degrees of freedom per particle, being three for the position and two for the direction. The 5-dimensional phase space is defined by the Cartesian product $\mathbb{R}^3 \times S^2$, where $\mathbb{R}^3$ is the $3D$ Euclidean space and S^2 is unit sphere in $\mathbb{R}^3$.

In order to characterize a particle configuration, it is necessary to specify all the degrees of freedom of each particle at each time instant, which corresponds to discrete points in the phase space. Analogously, it is possible to relate this discrete configuration to a continuous particle configuration, called phase space density, denoted by:

$$n(x, \omega, t)drd\omega. \tag{1}$$

The expression (1) represents the number of particles in a differential volume dr over the point $x \in \mathbb{R}^3$ that moves in a direction defined by the differential solid angle $d\omega$, $\omega \in S^2$ at the instant t. Its unit of measure is given by $m^{-3}sr^{-1}$. Note



Rendering Equation, Fig. 1 Flow in phase space

that the phase space density makes no mention of material-related attributes such as mass or energy. These concepts only appear when physical meanings are related to the studied particles. This abstract nature of the phase space density makes possible its use in almost every type of particle transport problem (Arvo 1993).

Generally it is convenient to characterize the particles density by flow through a real or imaginary surface. Consider the particles that cross a differential area dA with directions along the differential solid angle $d\boldsymbol{\omega}$ relative to the surface normal, at the time instant t. The particles are within the volume element $dAds$, where $ds = cdt$, as illustrated by Fig. 1. Assuming that x is a point inside the volume element, the number of particles is given by:

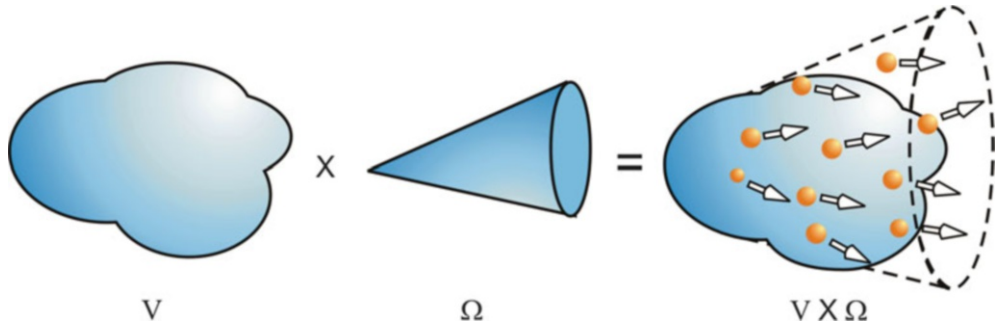
$$n(x, \omega)dAdsd\omega. \tag{2}$$

As $ds = cdt$, then:

$$cn(x, \omega)dAdtd\omega. \tag{3}$$

Particle Balance Equation

This section used as its main reference the Arvo work (Arvo 1993) and aims to derive a balance equation for particles that do not interact with each other. It is a widely used equation in Radiation Transport. It is an Eulerian derivation, since it takes into account a fixed reference.



Rendering Equation, Fig. 2 Phase space

Particles contained in some fixed volume in the phase space are considered. In this way, $V \subset \mathbb{R}^3$ is an arbitrary volume, $\Omega \subset S^2$ is an arbitrary solid angle, and consider the phase space defined by the Cartesian product $V \times \Omega$. This space contains all pairs (r, ω), such that $r \in V$ and $\omega \in \Omega$, as illustrated in Fig. 2.

The goal is to determine how the set of particles in $V \times \Omega$ changes over time. At any time t, the number of particles in this volume $(N(t))$ can be obtained by integrating the phase space density (given by the Eq. 1) in the volume:

$$N(t) = \int_{\Omega}\int_{V} n(r, \omega, t)\, dr d\omega, \tag{4}$$

which results in a dimensionless quantity.

Once the particles number in the volume of interest is obtained, their variation in time is analyzed. In general, the particles number in a given volume may change over time due to the properties of medium and time-dependent sources or due to transient effects as the system progresses in search of equilibrium. However, one only has to consider stationary distributions, since the speed of light is extremely fast. In this way, it is possible to assume that the equilibrium is reached instantaneously with respect to the geometric configuration of the environment at any instant of time.

Each volume then has a fixed number of particles, which implies that the phase space flux is independent of time, $\Phi = \Phi(r, \omega)$. Thus:

$$\frac{dN(t)}{dt} = 0. \tag{5}$$

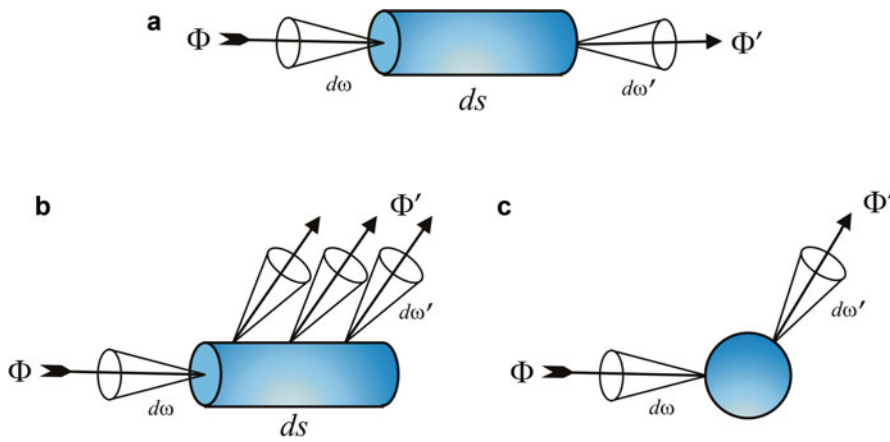
Even in the stationary case, time is evident in the constant movement of particles, implying that equilibrium is dynamic. The inflow and outflow of the volume must be in equilibrium, and to examine this balance it is necessary to identify the possible physical processes for which N can change. Each of the processes, namely emission, transmission, and collision, can change the number of particles in the volume. In this way, it is necessary that:

$$\begin{bmatrix}\text{Changes}\\ \text{due}\\ \text{Emission}\end{bmatrix} + \begin{bmatrix}\text{Changes}\\ \text{due to}\\ \text{Transmission}\end{bmatrix} + \begin{bmatrix}\text{Changes}\\ \text{due to}\\ \text{Collision}\end{bmatrix} = 0. \tag{6}$$

We will name the first term, *Changes Due to Emission,* for M_E. This term refers to generation of new particles through sources. It is assumed that there are one or more physical processes generating new particles and their combined effects are described by a source function (q) of phase space, defined in $\mathbb{R}^3 \times S^2$. This function gives the number of particles generated per unit volume, per unit of solid angle, and per unit time. Thus, its unit of measure is given by $m^{-3}sr^{-1}s^{-1}$. In terms of q, the change in N due to emission is given by:

$$M_E \equiv \int_{\Omega}\int_{V} q(r, \omega)\ \ dr d\omega, \tag{7}$$

and its unit of measure is s^{-1}.



Rendering Equation, Fig. 3 An intuitive view of volumetric interactions

We will name the second term, *Changes due to Transmission,* by M_T. This term refers to particles with directions in Ω that escape from or enter the volume V due to transmission. More precisely, transmission (or leakage) is the flow of particles passing through the surface ∂V of volume V. The leakage through each differential element of the surface depends only on the flow component that is normal to the surface. Integrating the normal component of the flux of particles in Ω over the entire surface ∂V gives:

$$M_T \equiv \int_{\Omega}\int_{\partial V} \Phi(s,\omega)\omega \cdot \mathbf{n}(s)\ \ drd\omega, \qquad (8)$$

and its unit of measure is s^{-1}. In general, some differential elements of the surface have positive flow and some negative flow, that is, M_T deals with particles entering and leaving the volume.

The third and last term, *Changes due to Collision*, is divided into two: absorption and scattering. As stated at the beginning of this section, it is assumed that the particles interact only with the environment, but do not interact with each other, which makes the collision rate independent of the flow.

It is assumed that the probability of particles disappearing due to absorption is proportional to the distance of displacement through the medium, as illustrated by Fig. 3a. The proportionality constant is called the *absorption coefficient* (σ_a), whose unit of measure is m^{-1}. This coefficient may vary with position, but is usually assumed to be independent of direction. This is equivalent to assuming that the medium is isotropic. The change in N due to absorption is given by:

$$C_{abs} = \int_{\Omega}\int_{V} \sigma_a(r)\Phi(r,\omega)drd\omega. \qquad (9)$$

Collisions due to scattering are more complex. As with absorption, the probability of a collision due to scattering occurs is proportional to the displacement distance of the particle. After collision, however, the new direction must be taken into account. Because of the hypothesis that particles move at a constant velocity, we need to consider other changes to the particles as a result of scattering.

The scattering process is characterized by the *volumetric scattering nucleus* (k). The function k is defined in $\mathbb{R}^3 \times [-1, 1]$, such that the probability of a particle r moving in a direction ω deflect to the new direction ω' (per unit of solid angle, per unit of displacement) is given by:

$$k(r; \omega \cdot \omega')\, drd\omega', \qquad (10)$$

and its unit of measure is $m^{-1}sr^{-1}$. Figure 3b illustrates this concept. The fact that k depends only on the scalar product $\omega \cdot \omega'$ and not from the individual directions confirms once again the isotropy of the medium.

Scattering can remove particles of $V \times \Omega$ through a process called *out-scatter*. In this process, the particle remains at V while its direction is instantly modified to something outside Ω, due to collision. To consider out-scatter, it is defined the total number of collisions due to scattering suffered by the particles in $V \times \Omega$ per unit time, given by:

$$C_{\text{out}} \equiv \int_{\Omega}\int_{V}\int_{S^2} k(r;\omega\cdot\omega')\Phi(r,\omega)d\omega' dr d\omega. \tag{11}$$

The opposite process to out-scatter is a process in which particles are added in $V \times \Omega$ because they have been deflected into the volume. This process is called *inscatter* and is defined as the number of particles in V, per unit time, with directions of displacement in Ω after scattering. It is given by:

$$C_{\text{in}} \equiv \int_{\Omega}\int_{V}\int_{S^2} k(r;\omega'\cdot\omega)\Phi(r,\omega')d\omega' dr d\omega. \tag{12}$$

Note that both C_{out} and C_{in} deal with particles whose directions are defined in Ω before and after scattering, which does not imply loss or gain. However, it is only necessary to consider the change due to scattering, which is defined by the difference between C_{in} and C_{out}. Once we have defined all the terms involved in the balance Eq. 6, we can now group the terms corresponding to the five physical processes capable of modifying N, separating into losses and gains:

$$\underbrace{M_T + C_{abs} + C_{\text{out}}}_{\text{losses}} = \underbrace{M_E + C_{\text{in}}}_{\text{gains}} \tag{13}$$

To extract the global balance equation from (13), it is necessary to eliminate the references to the fixed sets V and Ω. Note that all terms minus one of the Eq. 13 imply integration into V, only the term M_T is expressed as an integral in ∂V. In this way, it is possible to use the Gauss Theorem to convert it into a volume integral:

$$M_T \equiv \int_{\Omega}\int_{V} \omega\cdot\nabla\Phi(r,\omega)dr d\omega. \tag{14}$$

In addition to the Gauss Theorem, we also used the identity:

$$\nabla\cdot[\omega\Phi(r,\omega)] = \omega\cdot\nabla\Phi(r,\omega). \tag{15}$$

With the new expression for M_T, all terms in the Eq. 13 imply integration over V and Ω. However, the initial hypothesis was that $V \times \Omega$ is arbitrary, which allows to extract integrands:

$$\begin{aligned}&\omega\cdot\nabla\Phi(r,\omega) + \sigma_a(r)\Phi(r,\omega)\\ &+\int_{S^2} k(r;\ \ \omega\cdot\omega')\Phi(r,\omega)d\omega' = q(r,\omega)\\ &+\int_{S^2} k(r;\ \ \omega'\cdot\omega)\Phi(r,\omega')d\omega'.\end{aligned} \tag{16}$$

The integral corresponding to term C_{out} on the left side of the above equation can be simplified, since the Φ function does not depend on the integration variable. In this way, we introduce the *scattering coefficient* (σ_s), which is the probability of a particle suffering a scatter collision per unit of displacement, defined by:

$$\sigma_s(r) \equiv \int_{S^2} k(r;\omega_o\cdot\omega')d\omega', \tag{17}$$

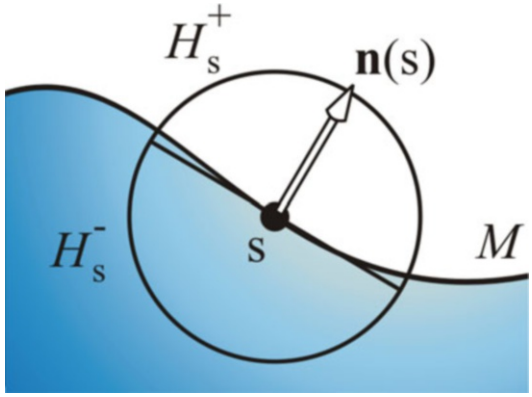
and its unit of measure is m^{-1}. The direction ω_o may be arbitrary in S^2 due to isotropy. In this way, σ_s becomes a factor of Φ in the balance equation.

In this way, replacing the new notations in the Eq. 16, we have:

$$\begin{aligned}&\omega\cdot\nabla\Phi(r,\omega) + \sigma_a(r)\Phi(r,\omega)\\ &+\sigma_s(r)\Phi(r,\omega) = q(r,\omega)\\ &+\int_{S^2} k(r;\omega'\cdot\omega)\Phi(r,\omega')d\omega'.\end{aligned} \tag{18}$$

The two factors, σ_s and σ_a, can be grouped into a *total interaction coefficient* o, which is the probability of a particle suffering the two types of collision, per unit of displacement, and is given by:

$$\sigma(r) \equiv \sigma_s(r) + \sigma_a(r), \tag{19}$$



Rendering Equation, Fig. 4 Partition of surface M

And its unit of measure is m^{-1}. Substituting in the Eq. 18, we have:

$$\omega \cdot \nabla \Phi(r,\omega) + \sigma(r)\Phi(r,\omega) = q(r,\omega) + \int_{S^2} k(r;\omega' \cdot m)\Phi(r,\omega')d\omega' \quad (20)$$

The Eq. 20 is an integral-differential equation for the transport of stationary particles in monovelocity. When time-dependent phenomena are considered, the phase space flux is a function of time, $\Phi = \Phi(r, \omega, t)$, and an additional term appears on the left side of the Eq. 20:

$$\frac{1}{c}\frac{\partial \Phi(r,\ \omega,\ t)}{\partial t}, \quad (21)$$

where c is the particle velocity.

Boundary Conditions

In this section, we evaluate the boundary conditions for the Eq. 20. It is necessary to verify what happens in the surfaces, collectively denominated M. Each point on the surface M imposes a natural partition of S^2 on two hemispheres, as illustrated in Fig. 4.

Let $\mathbf{n}(s)$ be the normal vector on the surface at point $s \in M$. It is defined as *positive hemisphere* where $\mathbf{n}(s) \cdot \omega > 0$, giving the set:

$$H_s^+ \equiv \{\omega \in S^2 : \omega \cdot \mathbf{n}(s) \geq 0\}. \quad (22)$$

Similarly, we define the collection of every pair (s, ω) corresponding to the rays originating in M and pointing off the surface:

$$H^+ \equiv \{(s,\omega) \in M \times S^2 : \omega \in H_s^+\}. \quad (23)$$

The *negative hemisphere* H_s^- and the set H^- are analogously defined, satisfying:

$$H_s^+ \cup H_s^- = S^2$$
$$H^+ \cup H^- = M \times S^2.$$

The explicit boundary condition is independent of the flow Φ, taking into account particles that are generated by independent processes and subsequently enter the system across boundaries. It is given by:

$$\Phi(s,\omega) = q_b(s,\omega), \quad \forall (s,\omega) \in H^+. \quad (24)$$

There are two types of *implicit boundary conditions*. The first is due to *specular reflection,* given by:

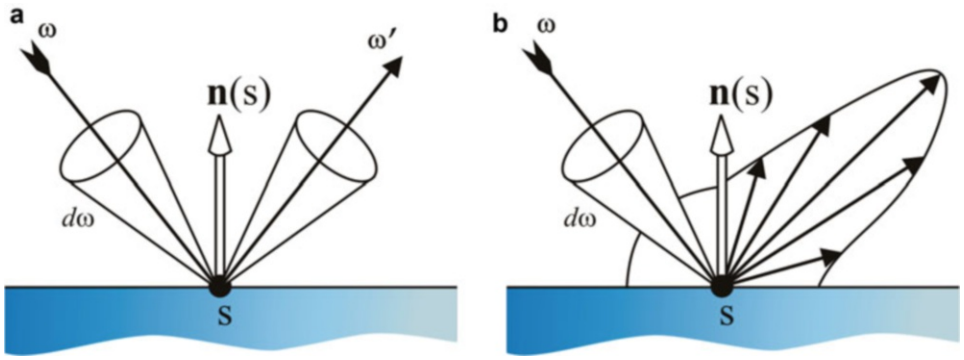
$$\Phi(s,\omega) = F(s,-\omega')\Phi(s,-\omega'), \quad (25)$$

where ω' is reflection direction of ω around normal surface in s.

The second type is given by an integral transformation that expresses the reflected density of particles in any direction as a weighted sum of incident densities, and the weight factor strongly depends on both directions. This phenomenon is also known as *diffuse directional reflection*, given by:

$$\Phi(s,\omega) = \int_{H_s^-} k_b(s;\omega' \rightarrow \omega)\Phi(s,\ \omega')d\omega', \quad (26)$$

where k_b is the surface scattering core with sr^{-1} unit of measure. The $\omega' \rightarrow \omega$ notation indicates incident and reflected directions. The following Fig. 5 illustrates the implicit boundary conditions.



Rendering Equation, Fig. 5 Two types of implicit boundary conditions: (**a**) specular reflection and (**b**) diffuse directional reflection

Radiometry

Radiometry provides a set of ideas and mathematical tools to describe the propagation and reflection of light (Pharr and Humphreys 2004). It deals with the measurement of various physical quantities related to the transport of radiant energy. The letter Q is used to represent the radiant energy, which is measured in Joules (J). The main radiometric quantities are: *radiant power* (or flux), *radiance, irradiance, radiosity,* and *intensity.*

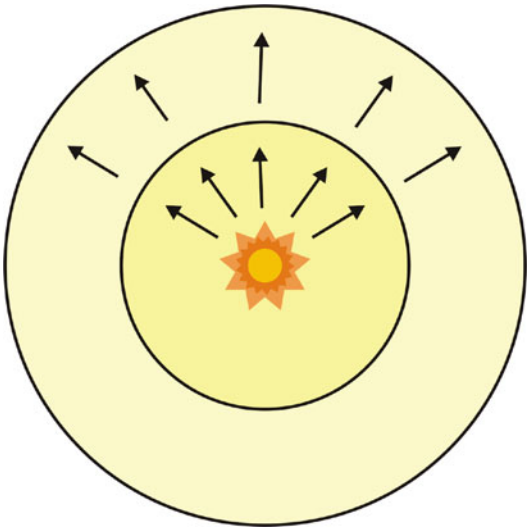
This section used as main reference the works (Gomes and Velho 2008; Pharr and Humphreys 2004), and its purpose is to report the properties of each radiometric quantity mentioned above. The Appendix A brings important mathematical concepts to the study of radiometry.

Radiant Power

The propagation of light occurs at a very high speed. In this way, it becomes more appropriate to think in terms of flow. Radiant power (Φ) (or flow) measures the rate of radiant energy flowing through a surface per unit time:

$$\Phi = \frac{dQ}{dt}. \tag{27}$$

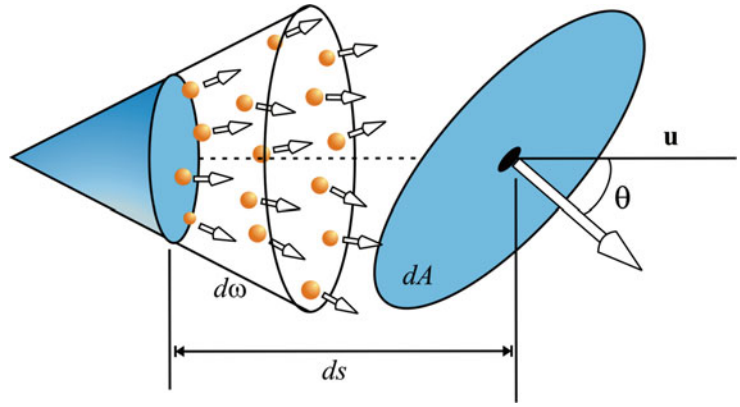
The magnitude called radiant power is measured in Watt ($1w = 1J/s$). The total emission of light sources is usually measured in terms of flow. Figure 6 illustrates the flow of a punctual light source measured by the total amount of energy that passes through an imaginary sphere around the light. It is interesting to note that the total amount of flow measured in both spheres is the same. It is also important to measure the flow per unit area. This magnitude is called flux density and is measured in w/m^2.



Rendering Equation, Fig. 6 Radiant power (or flow) from a punctual light source

Radiance

Consider a photon beam that flow in direction **u** through the surface element dA confined in the



Rendering Equation, Fig. 7 Photon beam in the volume element *dAds*

solid angle element $d\omega$. It is assumed that all photons are contained in the spatial volume element $dAds$, where $ds = cdt$, with c the photons velocity. Figure 7 illustrates the situation.

In previous sections, a particle model was introduced, where the number of particles in the phase space volume element is given by the expression (3). In addition, from what is presented in Appendix A, the projected area will be given by the expression (73), which gives $dA = dAcos\theta$. Each photon has an energy given by $\hbar v$, where $\hbar$ is the *Planck constant,* and v is the photon frequency. Therefore, the radiant energy carried by the photons in the volume element $dAcos\theta dmds$ is given by:

$$\hbar vcn(x, \mathbf{u}) dAcos\theta d\omega dt. \tag{28}$$

The radiant energy element dQ carried in the volume element $dAcos\theta d\omega$ is obtained by integrating the expression (28) into the phase space:

$$dQ = \left(\int_{\omega} \int_{A} \hbar vcn(x, \ \mathbf{u}) aAcos\theta d\omega \right) dt. \tag{29}$$

It is concluded that the radiant power is given by:

$$\phi = \frac{dQ}{dt} = \int_{\omega} \int_{A} \hbar vcn(x, \mathbf{u}) dAcos\theta d\omega, \tag{30}$$

and therefore:

$$\frac{d^2\phi}{dAcos\theta d\omega} = \hbar vcn(x, \ \mathbf{u}). \tag{31}$$

The magnitude of the Eq. 31 is called *radiance* and is indicated by the symbol L. In this way:

$$L = \frac{d^2\phi}{dAcos\theta d\omega} \ \Leftrightarrow \ d^2\phi = LdAcos\theta d\omega. \tag{32}$$

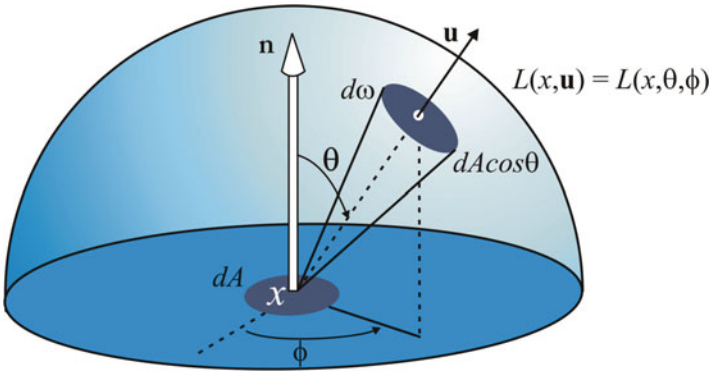
The unit of radiance is w/m^2sr. From the definition of radiance we have that:

$$L = \frac{d}{d\omega} \left(\frac{d\phi}{dAcos\theta} \right). \tag{33}$$

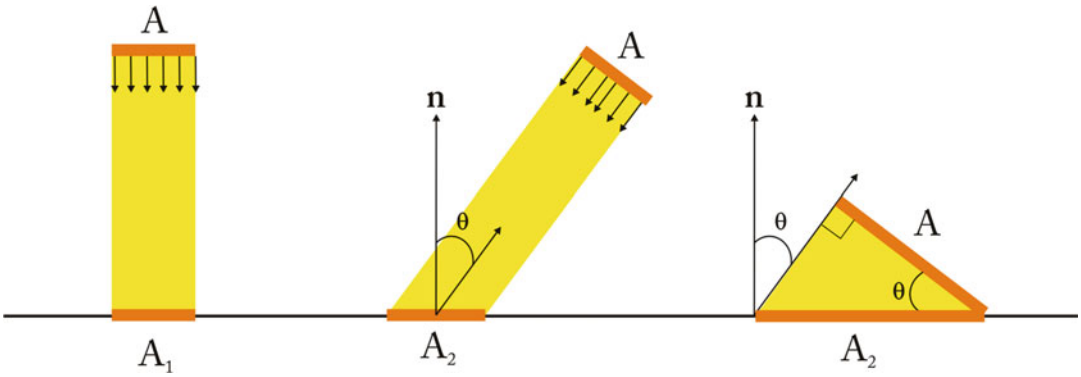
The expression in parentheses measures the density of radiant power ϕ on the projected surface in the normal direction. Therefore, radiance measures the radiant power density variation relative to the solid angle in a given direction.

More precisely, if $x \in \mathbb{R}^3$ is a point of space on a surface S and $\mathbf{u}$ is a direction, the radiance $L(x, \mathbf{u})$ is the flow at point x per unit of perpendicular area to $\mathbf{u}$ (i.e., projected area in propagation direction), and per unit of solid angle. Figure 8 illustrates the concept.

Integrating the expression $d^2\phi = LdAcos\theta d\omega$, given by the Eq. 32, in a given region R on a surface (integral in dA), and in the corresponding solid angle region (integral in $d\omega$), we obtain the total flux of radiant energy emitted by the region R within the specified solid angle. Further, by integrating the same expression with respect to the solid angle element throughout the upper hemisphere Ω, one obtains:



Rendering Equation, Fig. 8 Radiance emitted by a surface



Rendering Equation, Fig. 9 Lambert's Law

$$d\Phi = \left(\int_{\Omega} L(x, \ \theta, \phi) cos\theta d\omega \right) \ dA, \qquad (34)$$

or yet:

$$\frac{d\Phi}{dA} = \int_{\Omega} L(x, \ \theta, \phi) cos\theta d\omega, \qquad (35)$$

which is an expression for radiant power density throughout the upper hemisphere of the surface.

Irradiance and Radiosity

The radiometric magnitude *irradiance* (E) defines the incoming flux on a given surface through a given direction (flow per area unit). Irradiance is measured in w/m^2. Analyzing Fig. 6, while the flow has same measure in both spheres, the irradiance is smaller as the radius of sphere increases, because the area becomes larger. In particular, for sphere whose radius is given by r:

$$E = \frac{\Phi}{4\pi r^2}. \qquad (36)$$

The irradiance equation allows us to understand Lambert's Law, which says that the amount of light that arrives on a surface is proportional to the cosine of angle formed between the incident light direction and the vector normal to the surface.

According to the left side of Fig. 9, consider a light source with area A and flow Φ, whose direction incident on a given surface makes 0 with normal. The illuminated area A_1 of the surface is equal to the area A of the light source. Thus, the irradiance at any point in A_1 is given by:

$$E_1 = \frac{\Phi}{A}. \qquad (37)$$

Now consider the central part of Fig. 9, where the incident direction of light makes an angle θ with the normal. In this case, the illuminated area A_2 of the surface is greater than the area A of the light source and can be approximated by $A/cos\theta$ (as illustrated by the right side of Fig. 9). Thus, the irradiance at any point in A_2 is given by:

$$E_2 = \frac{\Phi cos\theta}{A}. \tag{38}$$

Generalizing, given a point x on a surface A and a direction $\mathbf{u} = (\theta_i, \phi_i)$ (where the subindex i indicates quantities associated with radiant energy entering the upper hemisphere of illumination), the *irradiance* E in x in direction $\mathbf{u}$ is the total flux density incident on the surface in specified direction. Using the Eq. 35 one has:

$$E = \frac{d\Phi}{dA} = \int_{\Omega} L_i(x, \ \theta, \phi) cos\theta d\omega. \tag{39}$$

This equation states that the total flux density incident on the surface is the integral of incident radiance in the direction $\mathbf{u}$ over the entire upper hemisphere. In particular, using spherical coordinates in the upper hemisphere, we obtain through the relation given by the Eq. 77:

$$\begin{aligned} E &= \int_{\Omega} L_i(x, \theta, \phi) cos\theta d\omega \\ &= \int_0^{\pi} \int_0^{2\pi} L_i(x, \theta, \phi) cos\theta sen\theta d\theta d\phi. \end{aligned} \tag{40}$$

Deriving the Eq. 39 with respect to the solid angle ω gives:

$$\begin{aligned} \frac{dE}{d\omega} &= L(x, \theta, \phi) cos\theta \Rightarrow dE \\ &= L(x, \theta, \phi) cos\theta d\omega. \end{aligned} \tag{41}$$

Radiosity defines the flux leaving a surface in a given direction. The radiosity B at a given point x of a surface in a direction (θ_o, ϕ_o) (where the subindex o indicates quantities associated with the radiant energy leaving the upper hemisphere of illumination) is the flux density emanating from the surface at point x, in the specified direction. Equivalent to the above irradiance equations, we have that:

$$B = \frac{d\Phi}{dA} = \int_{\Omega} L_o(x, \ \theta, \phi) cos\theta d\omega. \tag{42}$$

Using the expression of the solid angle element in the sphere (Eq. 77) we obtain:

$$\begin{aligned} B &= \int_{\Omega} L_o(x, \ \theta, \phi) cos\theta d\omega \\ &= \int_0^{\pi} \int_0^{2\pi} L_o(x, \ \theta, \phi) cos\theta sen\theta d\theta d\phi. \end{aligned} \tag{43}$$

Radiant Intensity

Radiant intensity I is the radiant flux emitted in a certain direction, which can be measured by the infinitesimal radiant flux in a given element of solid angle:

$$I = \frac{d\phi}{d\omega}. \tag{44}$$

The unit of measure is *w/sr*. Intensity describes the directional distribution of light and has meaning only for punctual light sources.

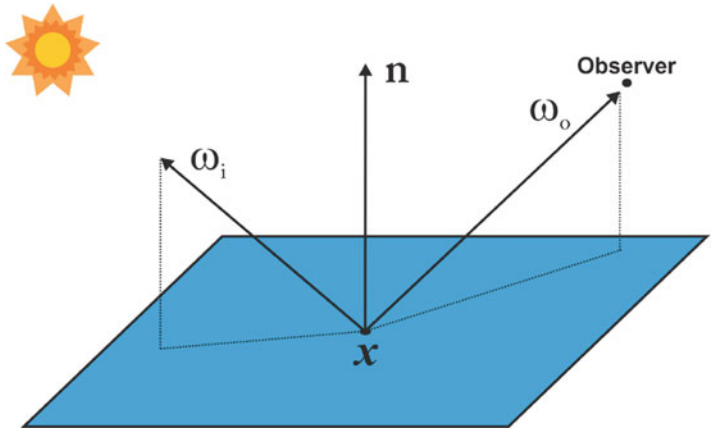
Now consider a surface located at a distance d from the light source so that its normal vector makes an angle θ with the direction of illumination. The solid angle element of this surface is given by $d\omega = dAcos\theta/r^2$. If E is the irradiance in the area element dA of the surface, we have that:

$$E = \frac{d\phi}{dA} = \frac{d\phi cos\theta}{r^2 d\omega} = \frac{1}{r^2} \frac{d\phi cos\theta}{d\omega} = \frac{I cos\theta}{d^2}. \tag{45}$$

This is the law of attenuation of radiant intensity with the square of distance.

Bidirectional Reflectance Distribution Function (BRDF)

In the physical world, objects have a different appearance when viewed from different positions, illuminated with light sources coming from different directions, or even with lights of different colors or intensities. In order to represent the process of illumination through the computer, it



Rendering Equation, Fig. 10 Incident and reflected flow in an element of area

is also necessary to understand these phenomena and to search for mathematical models that allow the simulation of these light-object interactions.

Among the main elements that influence the radiance emitted by a surface S, the main ones are: lighting, surface reflectance properties, and position of the observer. For simplicity, it is assumed that the medium of propagation is nonparticipative.

The bidirectional reflectance distribution function (BRDF) relates the incident energy in a point x with the reflected energy. Consider the configuration of Fig. 10. We want to know how much radiance leaves the surface in the direction ω_o towards the observer, denoted by $L_o(x, \omega_o)$, resulting from the radiance incident along the direction ft toward the surface, denoted by $L_i(x, \omega_i)$.

Considering the direction ω_i, as a cone of differential directions, the differential radiance in x is given by:

$$dE(x, \omega_i) = L_i(x, \ \omega_i) \cos\theta_i d\omega_i. \tag{46}$$

An amount of differential radiance will be reflected in the direction ω_o due to irradiance. The model of geometric optics provides some hypotheses about the behavior of light (Pharr and Humphreys 2004). The linearity hypothesis is one of them and says that the combined effect of two input data on an optical system is always equal to the sum of effects of each input data individually. Thus, by the hypothesis of the linearity of geometric optics, the reflected differential radiance is proportional to the irradiance:

$$dL_o(x, O_o) \propto dE(x, \omega_i). \tag{47}$$

The proportionality constant defines the BRDF of the surface in particular for the pair of directions ω_i and ω_o. The BRDF is defined by the quotient between radiance of the reflected flux and the irradiance of incident flux:

$$f_r(x, \ \omega_i, \ \omega_o) = \frac{dL_o(x, \ \omega_o)}{dE(x, \ \omega_i)} = \frac{dL_o(x, \ \omega_o)}{L_i(x, \ \omega_i) \cos\theta_i d\omega_i}. \tag{48}$$

BRDF provides a way to quantitatively express the connection between the irradiance (incident flux per unit area) and the radiance (incident flux per unit area per unit of solid angle) reflected by the surface. For simplicity, it is assumed that the point of reflection is equal to the point of incidence x (there is no phenomenon of scattering) and that the irradiance depends only on the direction of incidence (θ_i, ϕ_i). Thus, the BRDF depends only on the incidence and reflection directions (hence the bi-directional adjective in the name):

$$f_r = f_r(x, \theta_i, \phi_i, \theta_o, \phi_o) = f_r(x, \omega_i, \omega_o). \tag{49}$$

By definition, L_o is smaller than L_i, except in cases where the surface is a light source. However, the cosine factor in denominator in Eq. 48 causes the BRDF not to be limited in the range [0, 1], being able to assume arbitrarily large values. Note that from Eq. 48 we have:

$$\frac{dL_o(x,\omega_o)}{dL_i(x,\omega_i)} = fr(x,\omega_i,\omega_o)cos\theta d\omega_i$$
$$= fr(x,\omega_i,\omega_o)\mathbf{n},\omega_i d\omega_i. \quad (50)$$

As the total radiance leaving the upper hemisphere is less than or equal to the radiance entering that hemisphere, integrating both members of this equation throughout the upper hemisphere Ω concludes that:

$$\int_{\Omega} f_r(x,\omega_i,\omega_o)\mathbf{n},\omega_i \ d\omega_i \leq 1. \quad (51)$$

This inequality is called the *BRDF energy conservation law*. It states that the total energy reflected in the upper hemisphere cannot exceed the total incident energy. In addition, the BRDF is reciprocal, that is, for every pair of directions ω_i and ω_o, we have that $f_r(x, \omega_i, \omega_o) = f_r(x, \omega_o, \omega_i)$.

The Transfer Equation

The transport Eq. 20 is a general equation, unrelated to a particular physical situation of interest. In this section, we try to relate the general equation to the case of radiant energy transfer, where particles are treated as photons. There are three properties of the photons that need to be incorporated into the model:

- Photons move at constant speed (in vacuum this velocity is a universal constant denoted by c).
- Each photon has an associated frequency, an internal attribute that determines its energy and affects its behavior.
- The photons trajectory is strongly influenced by the surfaces.

First, we relate the notion of phase space flow with the corresponding radiometric concept known as *radiance*. Radiance is the energy per unit area per unit of solid angle due to radiant energy passing through a projected area. This concept is similar to the one of phase space flow, lacking to relate the notion of energy by photon, which is related to its frequency:

$$E = \hbar v, \quad (52)$$

whose unit measure is in Joules (J), and $\hbar$ is the Planck constant. The relation between phase space flux and radiance L is given by:

$$L(r,\omega) = \hbar v \Phi(r,\omega) = c\hbar v n(r,\omega), \quad (53)$$

and its unit measure is in $W/m^2 \cdot sr$.

Similarly, it is necessary to relate the source function of the phase space q with an amount relative to the radiant energy. A volumetric source term is then defined by:

$$\varepsilon(r,\omega) \equiv \hbar v q(r,\omega), \quad (54)$$

and its unit measure is in $W/m^3 \cdot sr$.

The physical process of emission is a phenomenon relative to matter and then applies to the volume. Nevertheless, it is useful to think of an abstraction that allows surfaces to be emitting. We define a surface source term given by:

$$\omega_b(s,\omega) \equiv \hbar v q b(s,\omega), \quad (55)$$

and its unit measure is in $W/m^2 \cdot sr$.

The functions L, ε, and ε_b will have the same role as the related functions, with the additional being related to significant physical quantities to the transport of radiant energy. In addition, boundary conditions are also imposed, both explicit and implicit. In this way, the transport Eq. 20 can be written in terms of L:

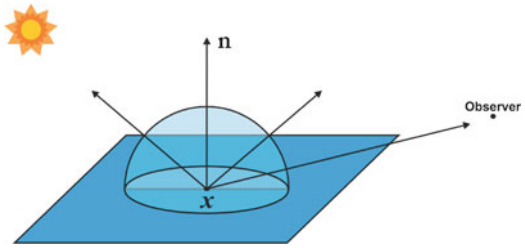
$$\begin{cases} \omega \cdot \nabla L(r,\omega) + \sigma(r)L(r,\omega) \\ = \varepsilon(r,\omega) + \int_{S^2} k(r;\omega' \cdot \omega)L(r,\omega')d\omega' \\ L(s,\omega) = \varepsilon_b(s,\omega) + \int_{H_s^-} k_b(s;\omega' \to \omega)L(s,\omega')d\omega' \end{cases} \quad (56)$$

Lighting Model

The illumination problem can be stated as follows (Gomes and Velho 2008):

Given a point $x \in S$ on a surface $S \subset \mathbb{R}^3$, a light source l and an observer at a point O,

determine the light energy L, from point x, which is perceived by the observer.



The illumination problem

We have seen that the lighting equation describes the propagation of radiant energy in space. In previous sections was presented a particle model, much used in radiative transport theory. In lighting, each particle is called a photon, which carries a certain amount of radiant energy. Illumination is the result of the movement of these photons. We defined radiant power (Φ), which is the radiant energy per unit of time.

Based on this information, if $dAd\omega$ is a volume element in phase space, the number of photons passing through dA in the neighborhood of the point x, under an infinitesimal element of solid angle $d\omega$ in direction ω, at time t, is given by:

$$\Phi(x, \omega, t) dA d\omega. \tag{57}$$

Light carries radiant energy, so we can consider the lighting equation as a problem in the area of transport theory, which studies the distribution of abstract particles in space and time. In order to obtain an expression of this equation, two hypotheses will be considered, namely, the system is in equilibrium and the medium is nonparticipative (Gomes and Velho 2008).

When the system is in equilibrium, the conditions of light propagation in the environment do not change during the simulated time interval. This condition implies that the flow is constant at all points of the scene:

$$\frac{\partial \Phi}{\partial t} = 0. \tag{58}$$

The hypothesis that the transmission occurs in a nonparticipative medium corresponds to suppose that the simulation is done in the vacuum. In this way, the only important phenomena happen on the surfaces of objects in the scene. The radiant energy transport in the vacuum between two points is given by the expression:

$$\Phi(r, \omega) = \Phi(s, \omega), \tag{59}$$

where r, s are points mutually visible in the direction ω, as illustrated in Fig. 11a.

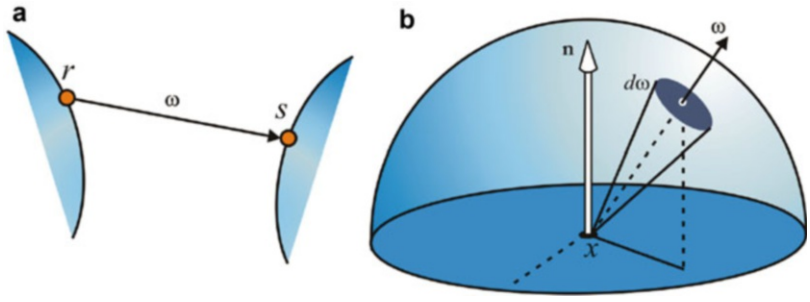
The Eq. 59 is valid for any pair of points in the surrounding space that satisfies the visibility condition. In particular, in computer graphics problems, the interest lies in the surface points of the scene. Given a point r, we find the point $s \in M$ using the *surface visibility function,* denoted by $v : \mathbb{R}^3 \times S^2 \rightarrow \mathbb{R}$, which returns the distance from the nearest visible point on a surface of the scene:

$$v(r, \omega) = inf\{\alpha > 0 : (r - \alpha\omega) \in M\}. \tag{60}$$

The point s is given by:

$$s = r - v(r, \omega)\omega. \tag{61}$$

The lighting function at a surface point x potentially depends on the flow of radiant energy coming in from all directions. In this way, the



Rendering Equation, Fig. 11 (**a**) Mutually visible points and (**b**) hemisphere of illumination

concept of *illumination hemisphere* Ω is used, which is defined by an imaginary unitary sphere whose center is at x (Gomes and Velho 2008). The luminous energy radiating from point x as well as the energy reaching the point x define a solid angle in the hemisphere. Thus, the illumination hemisphere controls all energy exchange between the surface point x and the environment around it, as illustrated by Fig. 11b.

Boundary Conditions

To formulate the illumination problem completely, it is necessary to define the boundary conditions, or what happens when light rays reach surfaces in the scene. According to Gomes and Velho (2008), there are two boundary conditions, the explicit and the implicit. In explicit condition the flow from a point s of the surface in direction ω is independent of the incident flux. This is the case with light sources. The lighting function is given by:

$$\Phi(s,\omega) = \mathcal{E}(s,\omega), \tag{62}$$

where $\mathcal{E}$ specifies the emissivity function of the surface.

In the implicit condition, the flux from a surface point s in direction ω depends on the incident flux in the illumination hemisphere. The function is given by:

$$\Phi(s,\omega) = \int_{\Omega_i} f_r(s,\omega_i,\omega_o)\Phi(s,\omega_i)d\omega_i, \tag{63}$$

where f_r is the BRDF.

The Radiance Equation

Based on everything seen in the previous sections, it is possible to state the radiance equation of a surface. In physical terms, the total radiance leaving a surface has two distinct sources: its own energy (emitted) and reflected energy:

$$\begin{aligned}\text{Total Radiance} = {} & \text{Radiance emitted} \\ & + \text{Radiance reflected.}\end{aligned} \tag{64}$$

To formulate the lighting equation, it starts with the transport equation between two points r and s:

$$\Phi(r,\omega) = \Phi(s \rightarrow, r, \ \omega), \tag{65}$$

where the notation $s \rightarrow r$ means the transport from s to r.

Border conditions need to be introduced. Thus, at each point r one wishes to obtain the contribution of radiant energy from all points s that are visible within the illumination hemisphere Ω_i in r. In this way, the right side of the Eq. 65 is replaced by the two boundary conditions (62) and (63):

$$\begin{aligned}\Phi(r,\omega_o) = {} & \mathcal{E}(s,\omega_o) \\ & + \int_{\Omega_i} f_r(s,\omega_i \rightarrow \omega_o)\Phi(s,\omega_i)d\omega_i,\end{aligned} \tag{66}$$

where s is determined by the visibility function v, given by expression (60). The transport Eq. 66 is a Fredholm integral equation of second type (Gomes and Velho 2008).

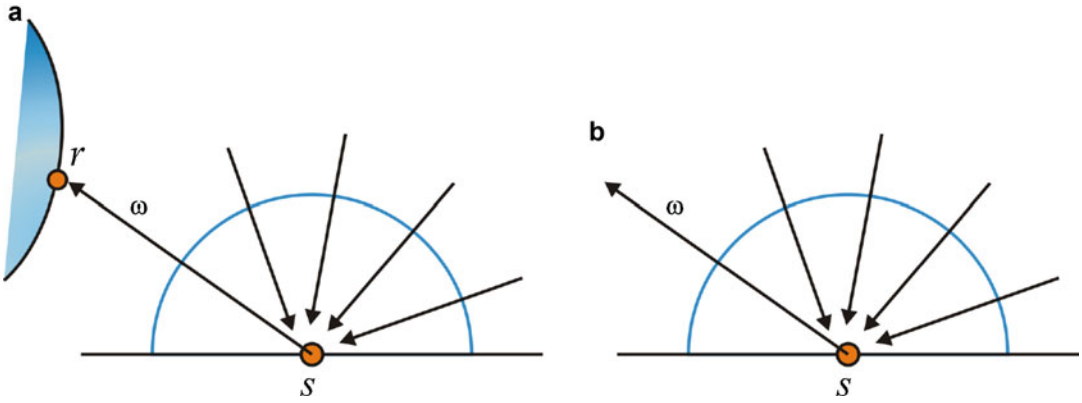
In order to obtain the total amount of radiant energy, the concepts of radiometry are used. The Eq. 33 defines the radiance magnitude L which is the radiant flux on a surface in a given direction, per unit of solid angle and per projected area. In this way, replacing this concept in the statement (64), we have that:

$$\begin{aligned}L(r,\omega_o) = {} & L_E(r,\omega_o) \\ & + \int_{\Omega_i} f_r(s,\omega_i \rightarrow \omega_o)L(s,\omega_i)cos\theta d\omega_i.\end{aligned} \tag{67}$$

The Eq. 67 is known as *radiance equation* or *rendering equation* (Kajiya 1986). The geometry is illustrated in Fig. 12a.

A modified version of the rendering Eq. 67 describes the energy radiated from a point s in direction ω in terms of the incident energy in the illumination hemisphere in s:

$$\begin{aligned}L(s,\omega_o) = {} & L_E(s,\omega_o) \\ & + \int_{\Omega_i} f_r(s,\omega_i \rightarrow \omega_o)L(s,\omega_i)cos\theta d\omega_i.\end{aligned} \tag{68}$$



Rendering Equation, Fig. 12 Geometries of rendering equation

This equation represents the total radiance of the energy coming out of a surface through the upper hemisphere. Its geometry is illustrated in Fig. 12b.

Rendering Calculation

The lighting equation, in general, must be solved numerically and approximate. To study the solution of the integral equation, the reference (Gomes and Velho 2008) proposes to use operator notations. If F is a function space, we define the integral operator $K : F \rightarrow F$, with:

$$(Kf)(x) = \int k(x, y) f(y)\, dy. \qquad (69)$$

The k function is called *core* of the operator. In this way, it is indicated that the K operator is applied in a function $f(x)$ by $(Kf)(x)$. Thus, one can write the rendering equation using the notation of operators:

$$L(r, \omega_o) = L_E(s, \omega_o) + (KL)(s, \omega_o), \qquad (70)$$

or $L = L_E + KL$.

The difficulty in solving the Eq. 70 lies in the fact that incognito function L appears on both sides of the equality. An approximate solution to the problem is the method of successive substitutions. The L function is defined recursively, so the Eq. 70 gives an expression for L. The basic idea is to substitute L for its expression on the right side of the equality, obtaining:

$$\begin{aligned} L &= L_E + K(L_E + KL) \\ &= L_E + KL_E + K^2 L \end{aligned}$$

where the exponent indicates the successive application of the operator K to a function f : $(K^2 f)(x) = (K(Kf))(x)$. Repeating the process $n + 1$ times:

$$\begin{aligned} L &= L_E + KL_E + \ldots + K^n L_E + K^{n+1} L \\ &= \sum_{i=0}^{n} K^i L_E + K^{n+1} L \end{aligned}$$

This recurrence relation provides an approximate way to calculate L. Ignoring the residual term of order $n + 1$, we have that:

$$L \approx L_n = \sum_{i=0}^{n} K^i L_E. \qquad (71)$$

The method of substitutions applied to the calculation of the lighting function has a very intuitive physical interpretation. The known term L_E corresponds to the radiant energy emitted by the light sources. The integral operator K models the propagation of reflected light on the surfaces. In this way, KL_E corresponds to the illumination of light sources which is reflected directly by the surfaces. Its successive application models the propagation of reflected light n times in the scene.

Appendix A

Mathematical Foundations

This appendix used as reference the work (Gomes and Velho 2008) and aims to highlight some important mathematical concepts for the study in question.

Spherical Coordinates

The unit sphere $S^2 \subset \mathbb{R}^3$, $S^2 = \{(x, y, z) \in \mathbb{R}^3; x^2 + y^2 + z^2 = 1\}$ has a natural parameterization, called *spherical coordinates,* which is based on the fact that each point of S^2 is characterized by the angles of longitude θ and latitude ϕ, as illustrated in Fig. 13.

From figure:

$$x = x(\theta, \phi) = cos\phi cos\theta;$$
$$y = y(\theta, \phi) = cos\phi sen\theta;$$
$$z = z(\theta, \phi) = sen\phi.$$

Solid Angle

The concept of solid angle is used in the definition of radiometric quantities by describing flows through a given region of a surface in a particular direction. To define a solid angle, one must define the concept of *spherical projection.*

Given a sphere $S^{n-1}(r)$ of radius r in $\mathbb{R}^n$ with center at the origin, the spherical projection is the transformation $p : \mathbb{R}^n - \{0\} \rightarrow S^{n-1}(r)$ defined by $p(x) = rx/|x|$. Geometrically this transformation projects the point x on the surface of the sphere along the radius that leaves the origin 0 of $\mathbb{R}^n$ and passes through x, as illustrated in Fig. 14.

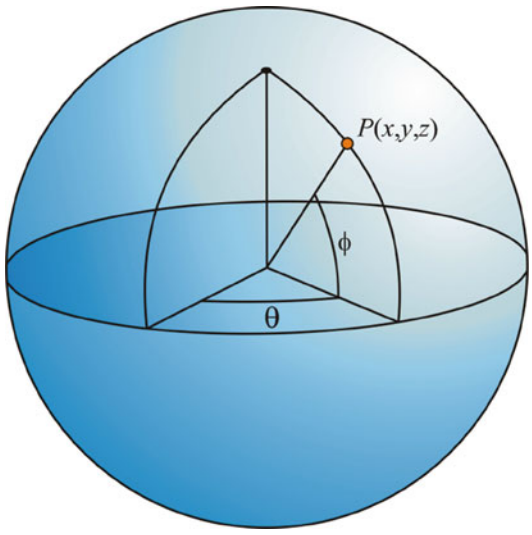
Consider a unit circle with center O. The concept of planar angle comes from the projection of an object in the circle. The measure of the arc of the circle containing the projection of the object corresponds to the planar angle.

The solid angle concept is an extension of the planar angle concept to measure the apparent area of objects in space. Consider a subset A of space, and a point O, which is the origin of observation. The measure of the solid angle ω determined by A is obtained as follows: we take a unit sphere S^2 with center in O and the spherical projection $p(A)$ of the set A on the sphere S^2. The area of $p(A)$ is the measure of ω. Figure 15a illustrates this concept.

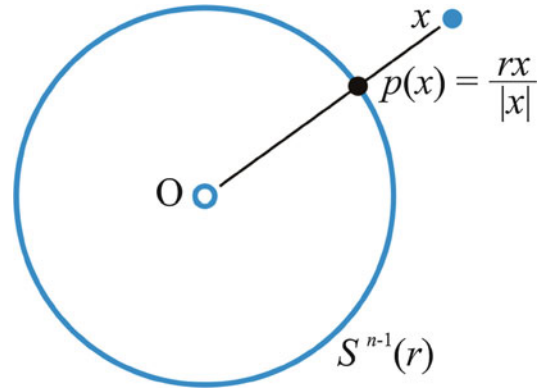
If it is necessary to take a sphere of radius r with center O, simply divide the projected area by the square of the radius. The measure of solid angle is given by:

$$\omega = \frac{\text{Area}(p(A))}{r^2}. \tag{72}$$

The spherical projection determines a cone of vertex O and base A, as illustrated in Fig. 15b.



Rendering Equation, Fig. 13 Spherical coordinates



Rendering Equation, Fig. 14 Spherical projection

This cone is the solid formed by the set of all semi-straight lines of the space originating from O and passing through points of the set A. The cone generalizes to three-dimensional space the geometric notion of the angular region of the plane geometry, and the Eq. 72 is a measure of this three-dimensional angular region.

According to Gomes and Velho (2008), both planar and solid angle are dimensionless quantities. In the first case, the arc length is divided by the radius of the circle, and in the second case an area is divided by the square of the radius length. However, the radian (*rd*) is used to indicate the measure of a planar angle and the stereo-radian (*sr*) as the unit of measure of a solid angle.

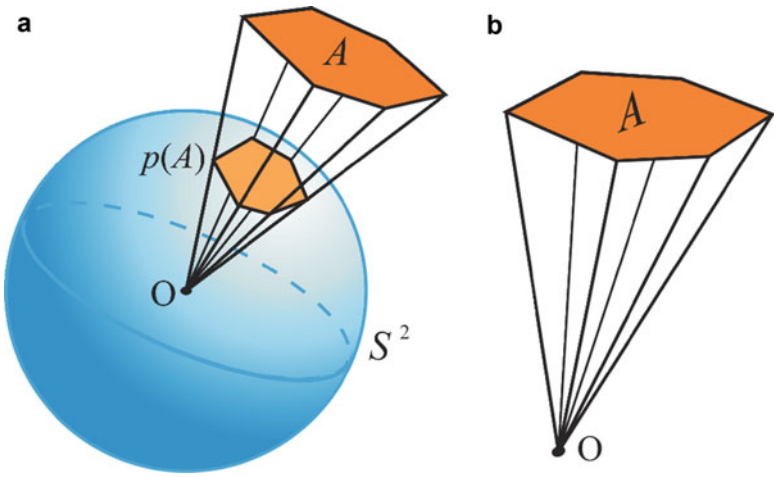
The light phenomena depend on the position of observer and therefore in general what matters is the projected area, which is the projection of the real area in the plane perpendicular to the radius of view. The projection of visualization is conical; however, if the area is very small in relation to the distance of the observer, it is possible to suppose that the projection is parallel (Fig. 16).

In this case, it is immediate to verify that the projected area is given by the product of real area A by cosine of the angle that the radius of vision does with the normal vector at the surface A:

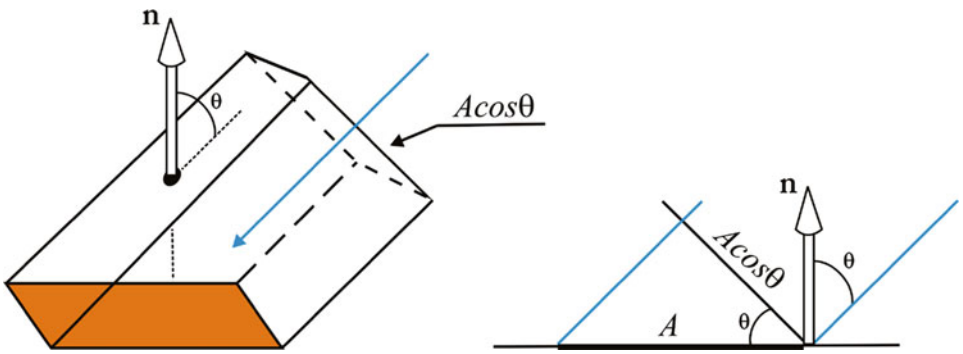
$$\text{rea projetada} = A\cos\theta. \tag{73}$$

Solid Angle Element

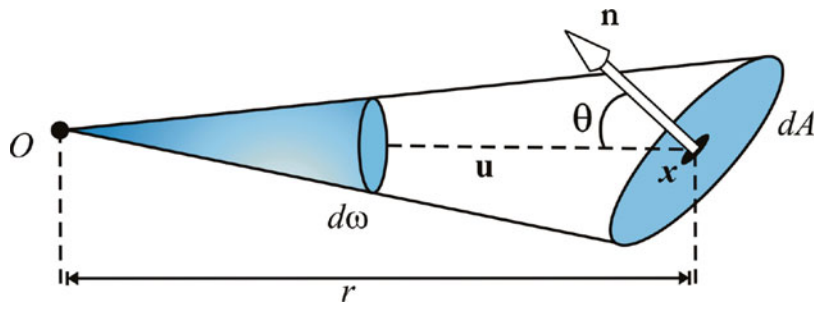
Radiometric quantities are defined by the use of rates of change of radiant energy entering or leaving a surface. In this way, it is important to define



Rendering Equation, Fig. 15 Notion of extended angle to measure the apparent area of objects



Rendering Equation, Fig. 16 Projected area



Rendering Equation, Fig. 17 Solid angle element

the infinitesimal elements of area (dA) and of solid angle ($d\omega$). Consider an area element dA of a surface A of space, and let $x \in A$ be a point of that area element at a distance r from the origin O, as illustrated in Fig. 17.

This element of area determines a solid angle element $d\omega$ from the point O in direction $\mathbf{u}$ defined by the origin O and the point x. By the definition of solid angle, the measure of $d\omega$ is given by:

$$d\omega = \frac{\text{Area}(p(dA))}{r^2}. \tag{74}$$

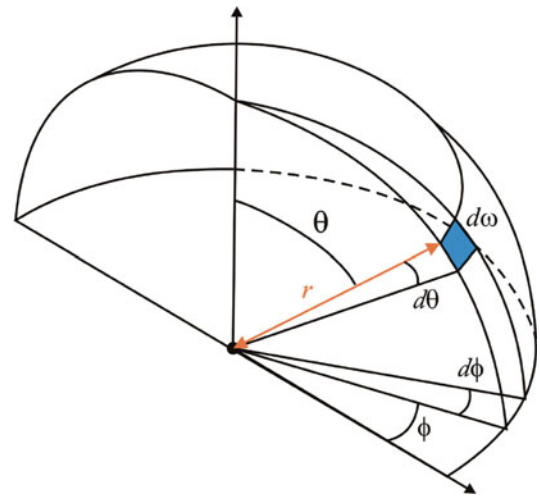
Since these are infinitesimal magnitudes, it is possible to suppose that dA is a flat surface and to replace the spherical projection by a parallel projection along direction $\mathbf{u}$. Using the Eq. 73 in the Eq. 74, we have that:

$$d\omega = \frac{dA\cos\theta}{r^2}. \tag{75}$$

The geometry of area dA can be arbitrary. In the case of a sphere, it is natural to represent the element of solid angle by a pyramid rather than a cone. Consider the sphere of radius r with spherical coordinates θ (azimuth) and ϕ (longitude) as illustrated in Fig. 18.

To determine the solid angle element at a point of spherical coordinates (ϕ, θ), one must define the area element dA of sphere. The planar angle element of a meridian passing through the point is $d\theta$, so the corresponding arc element is $rd\theta$.

The planar angle element of the equator is $d\phi$, projecting the point (ϕ, θ) in the plane of equator



Rendering Equation, Fig. 18 Solid angle element in spherical coordinates

we have that the projected radius is $rsen\theta$; therefore, the corresponding arc element is $rsen\theta d\phi$. The sphere area element dA is the product of these two arc elements:

$$dA = (rd\theta)(rsen\theta d\phi) = r^2 sen\theta d\theta d\phi. \tag{76}$$

Using Eq. 75, we obtain the measure of the infinitesimal element of the solid angle $d\omega$ in spherical coordinates:

$$d\omega = \frac{dA}{r^2} = sen\theta d\theta d\phi. \tag{77}$$

Integrating the volume element above into the whole sphere, one obtains the solid angle of the sphere:

$$\Omega = \int_0^{\pi}\int_0^{2\pi} sen\theta d\theta d\phi = 4\pi. \qquad (78)$$

Therefore, the solid angle of a hemisphere is 2π.

Prerendered graphics; Survival horror; Tank controls

Definitions

Survival horror: genre of game that puts emphasis on a horror atmosphere, limited weapons, and puzzle solving.

Prerendered graphics: graphical assets that appear 3D visually but rendered in game as flat 2D planes.

Tank controls: movement style that was used often in early 3D gaming. The term comes from the up command always pushing the character forward, and the down command always pushing the character backward. The character spins counterclockwise when the left command is pressed, and vice versa with the right command, similar to how a tank moves.

History

Resident Evil 2, often abbreviated as *RE2,* was first released on January 21, 1998, in North America. It is the sequel to the 1996 game *Resident Evil*, both developed by *Capcom*. *Resident Evil 2* serves as a direct continuation of the prior entries' story, taking place only months after the original game's conclusion. However, the game has a new

setting and cast of characters. After a viral outbreak at the Spencer Mansion rendering its inhabitants zombified bioweapons, the virus has now spread to Raccoon City.

Resident Evil 2 meant to capitalize on the success of the original and expand upon it. Because of this, the sequel has much higher production values than its predecessor. Environments and character models are more detailed. Voice acting is improved, the enemies have more variety, and the story is told through (at the time) cutting edge CGI cut scenes instead of the often-mocked live action cut scenes of the first entry. It continues the practice of having two playable characters with two separate campaigns. The original game's two separate campaigns play largely similar with the exception of interacting with different characters. The sequel ups the ante by having "A" and "B" scenarios. The campaigns are noticeably different, and events that happen in "Scenario A" will affect events in "Scenario B." Since each character has an "A" and "B" scenario, this brings the number of available campaigns to four.

Gameplay

The game plays similarly to its predecessor. 3D movement is controlled using tank controls in a static prerendered environment. This allows the developers to control the camera at all times, at the cost of visibility and mobility to the player. While this allows the developers to control the scares, it is often considered archaic by today's standards. The controls are considered a point of contention in gaming with some critics underlining that they are essential for a true survival horror experience, while others pointing out the poor design and their potential to inhibit the player more than to scare. The game progresses by the player finding items to solve puzzles, dispatching enemies and occasional bosses, and opening up the map using keys found in the environment. The game follows the story of two protagonists, Leon S. Kennedy and Claire Redfield, as they are trying to escape the Raccoon City which is under a zombie infestation. During the game, their paths cross with characters related with the Umbrella Corporation that initiated the zombie outbreak through a substance called G-virus, and their survival is tied to discovering the origins of the virus. Although *Resident Evil* is not the first survival horror franchise, it is the first to coin the term (Kirkland 2009). An emphasis on limited weapons and healing items, running from enemies instead of fighting them, and item management is what defines the game's experience. The game would go on to be a critical and commercial success (Metacritic n.d.; Eriksen 2020). It solidified the series as one of *Capcom*'s most lucrative franchises and has been ported to numerous systems over the years (as well as a movie adaptation franchise with mixed success; Lay 2007; Lukas 2009).

Production

In spite of the game's success, the production was incredibly troubled. Beginning only 1 month after the original's completion, development had to be scrapped when the game was around 60–80% completed. This version of the game, nicknamed *Resident Evil 1.5*, was radically different from the final product (Hurley 2018). While similar gameplay-wise, the original prototype had original environments, characters, story, and countless other assets that were all scrapped. Maintaining the scares of the original was important to the development team. Producer/series creator Shinji Mikami was unsatisfied with the original demo of the game and would later go on to say that the gameplay and locations were "dull and boring" (Whitehead 2012).

Remake

The game is often considered to be one of the best games on the original PlayStation and the series' 20+ year history, and the best game in the series' classic era. (As of November 2020, the original game has a 89/100 critic score and 9.2/10 user score on Metacritic.com https://www.metacritic.com/game/playstation/resident-evil-2) Leon

Kennedy and Claire Redfield continue to be the most popular characters in the franchise, and the setting of Raccoon City continues to be one of the most famous locations in gaming history (Ackerman 2019). The legacy of the game would lead to a successful remake (McWhertor 2019) that Capcom released on January 25, 2019. This reimagining would go on to sell 7.2 million copies, outselling the original. Ensuring that Leon and Claire's story would continue to be told to a whole new generation of gamers.

Sports Game

Definitions

Sports Simulator Game = a game made to mimic how sports are played.

Rocket League: A Sports Simulator Game

Rocket League is a sports simulator game developed and published by Psyonix. Its ESRB rating is E for everyone. Rocket League uses the Unreal three game engine. Rocket League first came out on the PlayStation 4 in 2015, and followed by the Xbox One, PC, and the Nintendo Switch in 2016. Rocket League features crossplay between all platforms. It is a multiplayer-focused game with several game modes ranging from one player versus one player to four players versus four players that last around 5 min. The concept of Rocket League is a soccer game but with cars instead of people (Zamora 2018).

The game's concept is simple as it is similar to soccer; players compete against others players in teams while controlling a rocket-powered car. There are many varieties of cars that players can customize in design and functionality. The target audience is competitive sports lovers and racing fans of any age group. In the main game mode, players chase a ball around to score in their opponent's net. There is a game mode called "Rumble" that is a variation on the original mode, but with added power-ups that change how the game is played. There are other game modes that focus around hockey, basketball, and a variation of volleyball. Lastly, players have the option to customize aspects of the game, such as goals needed to win, the ball's speed, gravity, car movements, etc. The basic movements and mechanics of the car involve boosting, flipping and jumping, and drifting. Players can combine boosting with jumping to propel their car in any direction. Using the ability to change direction in the air allows for more advanced shots of the ball than any ground-based gameplay would allow.

Rocket League is solely multiplayer. All the maps play the same with two goals and pads around the map to pick up the nitro. There is a simple leveling system. The max level is 75, taking months' worth of gameplay to achieve. The reason behind the lengthy time to max out a level is due to the fact that the sole way to get experience is simply by playing ranked matches. The leveling system also brings with it titles: level 1–9 is rookie, 10–19 is semi-pro, 20–29 is pro, 30–39 is veteran, 40–49 is expert, 50–59 is master, 60–73 is legend, and finally 74–75 is rocketeer. It takes 10,462,750 experience to get to the max level, which is reachable at least after several weeks of playing. The interface is very simple; it is a third-person view of the vehicle in the game, along with the time limit and score in the game.

The game was well received by critics and had a large fan base at launch that has gotten smaller as the game progressed; however, their current fan base is extremely loyal. Gabriel Zamora, writing in PC Magazine, praised the action elements of the game while criticizing the game's camera and high skill curve. "To say Rocket League is exhilarating is an understatement. Shooting through the sky to make a last-minute save, vaulting over your opponent to slap the ball out of their possession, or racing up a wall to intercept an errant ball are just a few of the crazy maneuvers you can expect to see during a match of Rocket League. The beauty of

the game is that you get rewards for executing fundamentals, as well as goals scored, so you needn't compete with your teammates and hog the ball. Actions, such as assisting other players with a goal, centering the ball in front of your opponent's goal, or clearing your own goal of the ball, all earn you points, so playing defender or support is just as worthwhile as playing the attacker. In that way, Rocket League is FIFA on wheels." Ludwig Kietzman of GamesRadar admired the thrill of chasing the ball inside the arena. "The joy of Rocket League is in finding all the pre-nudge possibilities and permutations and becoming so attuned to your car's movements that explicit thinking evaporates, leaving only instinct in the eternal battle of who's gonna nudge next. You'll learn something new and minor almost every round: how much distance you can cover with the double-jump forward flip, or how high is too high for you to sail right below the ball in misguided anguish. There's the sideways flip-boost, sending the ball into the goal at a right angle; the glorious (but especially difficult) rocket flight above everyone else to snatch a ball from the heavens, the rude bump of an opponent to ruin their planned trajectory into a rocket-fuel pickup on the field. There is just as much skill to learn as there is to demonstrate by accident (don't worry, nobody will ask if it's the latter)." Kietzman critiqued the lack of a spectator mode to let other players view a match without playing and the XBOX One's version for not having an option to play with users from other consoles, although since the article was written both of these issues had been addressed (Kietzman 2016).

Psyonix had a marketing campaign that focused on getting attraction with streaming and video-sharing websites. Most of the current community started playing the game out of curiosity but stayed after they found a competitive scene. The community currently has a large following on several websites such as Youtube, Twitch, and Reddit (Needleman 2015). There is also a Rocket League eSports scene. The vice president of Psyonix contributes the success and the rise of the eSports scene to players who livestreamed the game on Twitch. "Twitch and its streamers have been an instrumental part of our success since we launched last July, and that made them a perfect match for us. We couldn't be more thrilled to be working with a team that we respect as highly as we do Twitch, and we can't wait to show the world what we can do in eSports together!" Matches are streamed live on Twitch and re-uploaded to YouTube to be viewed at later dates (Makuch 2016).

ROP-Skill System: Model in Serious Games for Universities

Geraldine Anna Berger
Department of Business Information Systems, Friedrich-Schiller University, Jena, Germany

Synonyms

Escape room; Game based learning; Pedagogy; Serious games; Skill system; Skill tree; Unity

Definition

The ROP-Skill System – the model was developed for Serious Games, which are used as interactive materials in universities to supplement content and as an extension for more complex problems. The model uses collected points for skilling new abilities, but if you have finished a bonus level, chosen a higher difficulty level, or used special artifacts the system switches to random for skilling.

Introduction

In the age of digitalization for higher education, medicine, or business, Serious Games are used as interesting interactive exercises. In terms of knowledge, diversity, and group dynamics, digital games allow universities to introduce complex subjects in new formats tailored to provide motivation for different educational levels. However, the development and the extension of content in Serious Games takes time, money, and staff. One possibility is the development and the usage of a Skill System for lecturers, which would change the content of skills but not the story. The ROP-Skill System – model is based on a decision tree with two different strategies: extend the learning content in a Serious Game and use the Self-Determination Theory (SDT) components for different types of motivation. In this entry, we discuss the theory, functionality, and benefits of the skill system – model for Serious Escape Games.

Educational Theory

The ROP-Skill System uses the self-determination theory (SDT) which refers to the flow experience (Chen and Hwang 2015), (Kiili et al. 2014), (Su and Hsaio 2015), and the Cognitive Evaluation Theory (CET) (Erhel and Jamet 2013), (Yang 2012). The flow theory with the flow experience concept by Csikszentmihalyi (Csikszentmihalyi 1990) and the extension of Kiili et al. (Kiili et al. 2014) with the playability shows the high potential in evaluating the quality of educational games. In this context, the flow experience can be defined as a complete state of engagement in a task, without distraction by thoughts or emotions. One argument is that students with higher self-determined motivation are more rapid to reach the flow experience and to be deeply engaged in their task (Lee 2005).

The cognitive evaluation theory (Ryan and Deci 2000) is based on different types of motivation. "The concept of intrinsic motivation (IM) refers to behaviors performed out of interest and enjoyment. In contrast, extrinsic motivation (EM) pertains to behaviors carried out to attain contingent outcomes" (Vallerand and Ratelle 2002).

In the SDT are different types of motivations relevant for a new action. In this context, Ryan and Deci found that "motivation concerns energy, direction, persistence, and equifinality – all aspects of activation and intention" (Ryan and Deci 2000b). Motivation can be separated into three categories (Table 1): amotivation, that is, a deficit of motivation, extrinsic motivation, that is, motivation for a specific external reward and intrinsic motivation, that is, motivation derived from one's own inherent interest or enjoyment (Ryan and Deci 2000; Deci and Ryan 2000).

In the educational context, the students need a certain level of competence and connection with other people (e.g., peers, teachers) to feel self-determined. The feeling of control in the learning task and their activities within the task shows that

ROP-Skill System: Model in Serious Games for Universities, Table 1 Self-determination in a context of regulation type and autonomy (Ryan and Deci 2009)

Intrinsic motivation	Extrinsic motivation				Amotivation
Intrinsic regulation	Integrated regulation	Identified regulation	Introjected regulation	External regulation	Non regulation
Highest relative autonomy	←			→	Lowest relative autonomy

the degree of autonomy corresponds with the students feeling in the classroom (Reeve 2002).

If a certain level of autonomy is allowed for students, the result shows that the students feel more competent, open-minded, and creative (Jang et al. 2010). It shows that students' perceptions of autonomy can be influenced by the "autonomy supportive" of the teacher. In the literature review by Talor et al. (Taylor et al. 2014), the SDT was extended by the Academic Motivation Scale (AMS) (Vallerand and Bissonnette 1992) and shows that a relation between STD and academic achievement is possible.

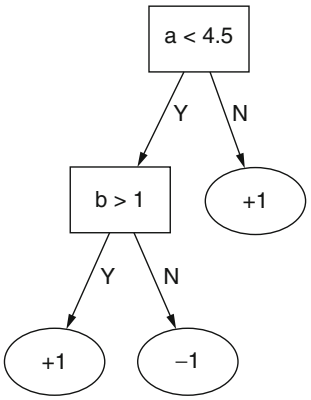
In a context where we are working to foster very specific components within the mechanics of the game (Bellotti et al. 2011), a model such as the ROP-Skill System is very helpful, because the level of autonomy is very high. The concept uses the self-determined motivation and fosters the learning in different steps.

Decision Tree

The ROP-Skill System is based on the principles of a decision tree (Fig. 1) (Freund and Mason 1999) and uses it for step by step learning. The development of the decision tree depends on the player's decisions, their chosen level of difficulty, and special items or completed bonus levels. If a player wants to reach the next skill, they need points or the activation of the "Random" mode. In the next section, we describe the ROP-Skill System – model and the rules for skilling. We analyze its impact on games in which it has been used so far.

ROP-Skill System – Model

The ROP (Random Or Points) Skill System – model (Fig. 2) uses two different strategies to unlock new skills.



ROP-Skill System: Model in Serious Games for Universities, Fig. 1 Decision tree

Points Strategy

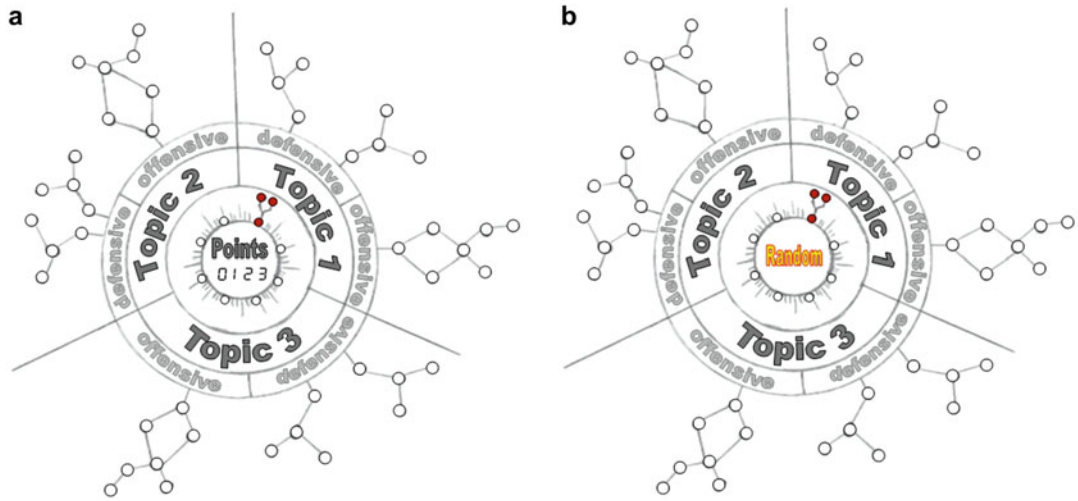
In the normal mode of the game, the player collects points, which are shown in the ball in the middle of the model, and uses them to improve their skills or equipment. In this context, the skillable options are adapted to the content of the module of the teacher. Since the model is designed for a duration of one semester, there are only a few available classes that represent the main topics of the module from the teacher's perspective. Whenever enough points are collected, a skill in a corresponding class is possible.

Random Strategy

The "random" skill mode is only activated automatically for certain events.

1. If a special item is used or it is in the player's inventory menu.
2. When a bonus level is completed.

If the random mode is active, the ball in the middle of the model changes from points to



ROP-Skill System: Model in Serious Games for Universities, Fig. 2 ROP-Skill System – Model (**a**) Using the "points strategy"; (**b**) the model switches to the Random-Mode

random and the selection pointer rotates like a wheel of fortune, which can be stopped with enter. The selection pointer comes slowly to a standstill in a class.

Once the appropriate class has been selected, the system now assigns a new skill corresponding to three modes of difficulty. This can be to the player's advantage or disadvantage.

Mode 1 (Easy): The menu pointer rotates slowly and when a class is selected by the player's strengths, that is, where the player has already assigned a skill, another skill is added. Otherwise one of the trees at level 1 is randomly skilled in an empty class.

Mode 2 (Normal): The menu pointer rotates with medium speed. After that a class is selected and randomly skilled.

Mode 3 (Hard): The menu pointer rotates quickly and when a class is selected, the player weakens, that is, only one skill point is added to the tree that has not been skilled before.

At the end of the random skill, the ball in the middle changes again from random to points. This also happens if a class is selected for the random skill that is already completed so that the random skill fails and the ball changes from random to points again.

Bonus Level

Each bonus level can be completed with each class of the corresponding level, because the bonus levels contain all elements of the corresponding classes.

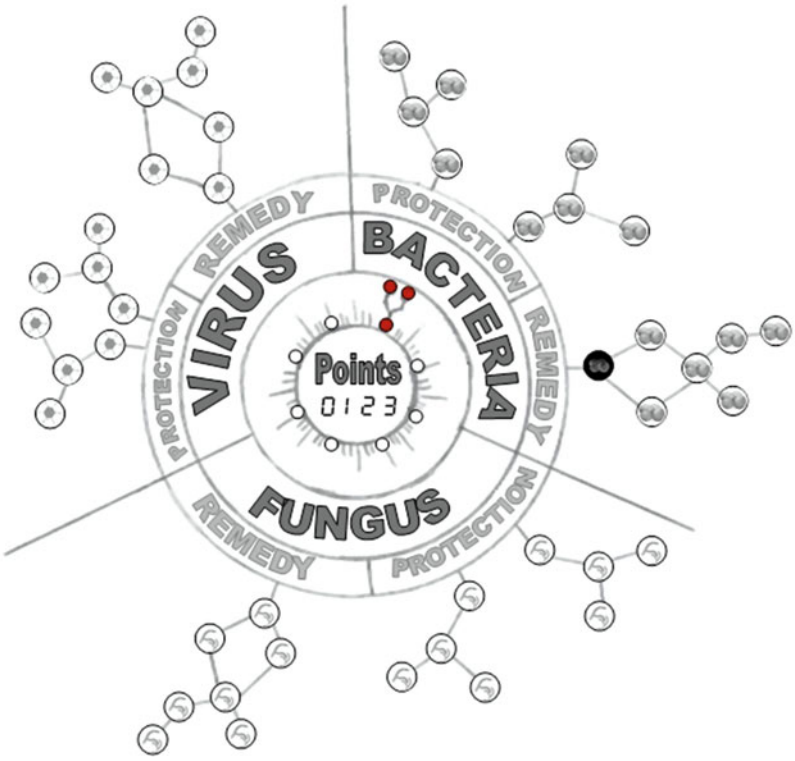
Special Items

If a particular item belonging to a class is equipped or used, more points can be collected or the probability of a random skill increases.

ROP-Skill System for a Practical Example in Biology

A practical example for using the ROP-Skill System is provided by the Serious Escape Game "Lysordion," which is currently in the conceptual phase and developed for the module "General Microbiology" for medicine, chemical engineering, and pharmaceutical biotechnology courses.

In "Lysordion," the player becomes ill with "Red Eye," a deadly plague, and is locked in a quarantined zone on a campus from which they have to escape. In 15 levels, the player solves a series of Escape Room puzzles to find a cure and protection from the plague. After each level, the player has the opportunity to improve their skills and learn new skills through the ROP-Skill System before the new escape room level starts.



ROP-Skill System: Model in Serious Games for Universities, Fig. 3 ROP-Skill system for the concept of "Lysordion"

For this module, the ROP-skill tree reduced main topics to three categories: bacteria, virus, and fungus. Each skill represents a historical experiment from the beginning to the modern era and contains instructions, which allows the player to do the experiment and to get previous knowledge.

In this example (Fig. 3), the points were used to collect new knowledge in the category "Bacteria" for the production of a remedy. The newly learned ability is marked in black. This skill introduces Griffiths' experiment on mice with *Streptococcus pneumoniae* and the instructions. The player can now carry out the experiment within the quarantined zone and try to identify the organism of "Red Eye." A special item here is, for example, the antique syringe from a showcase with which a random skill is possible in the experiment.

If the player skills in the wrong class during the game in the search for a cure for "Red Eye" and cannot find a cure, the game can still be completed with an alternative ending. Depending on the scenario, the player escapes with different outcomes.

Conclusion

The ROP-Skill System was designed for the lecturers in universities to optimize Serious Escape Games and reduce the content of one semester to a few classes. The using of two different methods for skilling makes the game more difficult, but also interesting and the modes of difficulty change the skill system to create new challenges. Special items and completed bonus levels are also rewarded by the system with a random skill and motivate to continue playing. In the educational context, the ROP-Skill System shows significant advantages to expand the content of Serious Games and represents a particularly promising field of research and development.

Artificial intelligence; Game AI; Real-time strategy games; RTS games

Definition

Real-time strategy (RTS) games is a subgenre of strategy games where players need to build an economy (gathering resources and building a base) and military power (training units and researching technologies) in order to defeat their opponents (destroying their army and base). Artificial intelligence problems related to RTS games deal with the behavior of an artificial player. This consists among others to learn how to play, to have an understanding about the game and its environment, and to predict and infer game situations from a context and sparse information.

Introduction

The field of real-time strategy (RTS) game artificial intelligence (AI) has advanced significantly in the past few years, partially thanks to competitions such as the "ORTS RTS Game AI Competition" (held from 2006 to 2009), the "AIIDE StarCraft AI Competition" (held since 2010), and the "CIG StarCraft RTS AI Competition" (held since 2011). Based on the work presented in Othman et al. (2012), here we first define RTS games, then list the open problems in creating AI for RTS games, and finally point to the approaches that have been proposed to address these problems.

Real-Time Strategy Games

From a theoretical point of view, the main differences between RTS games and traditional board games such as Chess are:

- RTS games are *simultaneous move* games, where more than one player can issue actions at the same time.
- Actions in RTS games are *durative*, i.e., actions are not instantaneous, but take some amount of time to complete.
- RTS games are "real time," which actually means that each player has a very small amount of time to decide the next move and that, in contrast to *turn-based* games, the game keeps advancing even if a player does not execute any actions. Compared to Chess, where players may have several minutes to decide the next action, in StarCraft, a popular RTS game, the game executes at 24 frames per second, which means that players can act as fast as every 42 ms, before the game state changes.
- Most RTS games are partially observable: players can only see the part of the map that has been explored. This is referred to as the *fog of war*.
- Most RTS games are nondeterministic: some actions have a chance of success, and the amount of damage dealt by different units is sometimes stochastic.
- And, finally, the complexity of these games, both in terms of state space size and in terms of number of actions available at each decision cycle, is very large. For example, the state space of Chess is typically estimated to be around 10^{50}, heads up no-limit Texas holdem

poker around 10^{80}, and Go around 10^{170}. In comparison, the state space of StarCraft in a typical map is estimated to be many orders of magnitude larger than any of those, as discussed in the next section.

For those reasons, standard techniques used for playing classic board games, such as game tree search, cannot be directly applied to solve RTS games without the definition of some level of abstraction or some other simplification. Interestingly enough, humans seem to be able to deal with the complexity of RTS games and are still vastly superior to computers in these types of games (Buro and Churchill 2012). For those reasons, a large spectrum of techniques have been attempted to deal with this domain, as we will describe below.

In the past few years, *StarCraft: Brood War* (an immensely popular RTS game released in 1998 by Blizzard Entertainment) has become the standard testbed for evaluating AI techniques in RTS games. StarCraft is set in a science-fiction-based universe where the player must choose one of the three races: Terran, Protoss, or Zerg. In order to win a StarCraft game, players must first gather resources (minerals and Vespene gas). As resources become available, players need to allocate them for creating more buildings (which reinforce the economy and allow players to create units or unlock stronger units), research new technologies (in order to use new unit abilities or improve the units), and train attack units. Units must be distributed to accomplish different tasks such as reconnaissance, defense, and attack. While performing all of those tasks, players also need to strategically understand the geometry of the map at hand, in order to decide where to place new buildings (concentrate in a single area or expand to different areas) or where to set defensive outposts. Finally, when offensive units of two players meet, each player must quickly maneuver each of the units in order to fight a battle, which requires quick and reactive control of each of the units.

From a theoretical point of view, the state space of a StarCraft game for a given map is enormous. For example, consider a typical 128 × 128 map. At any given moment, there might be between 50 and 400 units in the map, each of which might have a complex internal state (remaining energy and hit points, action being executed, etc.). This quickly leads to an immense number of possible states (way beyond the size of smaller games, such as Chess or Go). For example, just considering the location of each unit (with 128 × 128 possible positions per unit), and 400 units, gives us an initial number of $16384^{400} \approx 10^{1685}$. If we add the other factors playing a role in the game, such as resources, hit points, energy, research status, cool-down timers, etc., we obtain even larger numbers (see Othman et al. (2012) for a more in-depth description of the complexity of StarCraft).

Challenges in RTS Game AI

Early research in AI for RTS games (Buro 2003) identified the following six challenges: resource management, decision making under uncertainty, spatial and temporal reasoning, collaboration (between multiple AIs), opponent modeling and learning, and adversarial real-time planning. While there has been a significant work in many, others have been untouched (e.g., collaboration). Moreover, recent research in this area has identified several additional research challenges, such as how to exploit the massive amounts of existing domain knowledge (strategies, build orders, replays, and so on). Thus, the challenges in RTS game AI can be grouped in six main different areas, described below.

Planning As mentioned above, the size of the state space in RTS games is much larger than that of traditional board games such as Chess or Go. Additionally, the number of actions that can be executed at a given instant of time is also much larger. Thus, standard adversarial planning approaches, such as game tree search, are not directly applicable. As we elaborate later, planning in RTS games can be seen as having multiple levels of abstraction: at a higher level, players need long-term planning capabilities, in order to

develop a strong economy in the game; at a low level, individual units need to be moved in coordination to fight battles taking into account the terrain and the opponent. Techniques that can address these large planning problems by either sampling or hierarchical decomposition do not yet exist.

Learning Given the difficulties in playing by directly using adversarial planning techniques, many research groups have turned attention to learning techniques. We can distinguish three types of learning problems in RTS games:

- *Prior learning*: How can we exploit available data, such as existing replays, or information about specific maps for learning appropriate strategies before hand? A significant amount of work has gone in this direction.
- *In-game learning*: How can bots deploy online learning techniques that allow them to improve their game play while playing a game? These techniques might include reinforcement learning techniques, but also opponent modeling. The main problem again is the fact that the state space is too large and the fact that RTS games are partially observable.
- *Inter-game learning*: What can be learned from one game that can be used to increase the chances of victory in the next game? Some work has used simple game-theoretical solutions to select among a pool of predefined strategies, but the general problem remains unsolved.

Uncertainty Adversarial planning under uncertainty in domains of the size of RTS games is still an unsolved challenge. In RTS games, there are two main kinds of uncertainty. First, the game is partially observable, and players cannot observe the whole game map (like in Chess) but need to scout in order to see what the opponent is doing. This type of uncertainty can be lowered by good scouting and knowledge representation (to infer what is possible given what has been seen). However, scouting also means deliberately reducing economic progress in order to obtain information. Second, there is also uncertainty arising from the fact that the games are adversarial, and a player cannot predict the actions that the opponent (s) will execute. For this type of uncertainty, the AI, as the human player, can only build a sensible model of what the opponent is likely to do.

Spatial and Temporal Reasoning Spatial reasoning is related to each aspect of terrain exploitation. It is involved in tasks such as building placement or base expansion. In the former, the player needs to carefully consider building positioning into its own bases to both protect them by creating defenses or walls against invasions and to avoid bad configurations where large units could be stuck. In base expansion, the player has to choose good available locations to build a new base, regarding its own position and opponent's bases. Finally, spatial reasoning is key to tactical reasoning: players need to decide where to place units for battle, favoring, for instance, engagements when the opponent's units are lead into a bottleneck.

Analogously, temporal reasoning is key in tactical or strategic reasoning. For example, timing attacks and retreats to gain an advantage. At a higher strategic level, players need to reason about when to perform long-term impact economic actions such as upgrades, building construction, strategy switching, etc. all taking into account that the effects of these actions are not immediate but longer term.

Domain Knowledge Exploitation In traditional board games such as Chess, researchers have exploited the large amounts of existing domain knowledge to create good evaluation functions to be used by alpha-beta search algorithms, extensive opening books, or end-game tables. In the case of RTS games, it is still unclear how the significantly large amount of domain knowledge (in the forms or strategy guides, replays, etc.) can be exploited. Most work in this area has focused on two main directions: (1) hard-coding existing strategies into bots (so that bots only need to decide which strategies to deploy, instead of having to solve the complete planning problem) and (2) mining large datasets of replays (Synnaeve et al. 2012a; Weber and Mateas 2009) to automatically extract strategies, trends, or plans.

Task Decomposition Most existing approaches to play RTS games work by decomposing the problem into a collection of smaller problems to be solved independently. Specifically, a common subdivision is:

- *Strategy*: corresponds to the high-level decision-making process. This is the highest level of abstraction for the game comprehension. Finding an efficient strategy or counterstrategy against a given opponent is key in RTS games and concerns the whole set of units a player owns.
- *Tactics*: are the implementation of the current strategy. It implies army and building positioning, movements, timing, and so on. Tactics concerns a group of units.
- *Reactive control*: is the implementation of tactics. This consists in moving, targeting, firing, fleeing, and hit-and-run techniques (also known as "kiting") during battle. Reactive control focuses on a specific unit.
- *Terrain analysis*: consists in the analysis of regions composing the map: choke points, minerals and gas emplacements, low and high walkable grounds, islands, etc.
- *Intelligence gathering*: corresponds to information collected about the opponent. Because of the fog of war, players must regularly send scouts to localize and spy enemy bases.

In comparison, when humans play StarCraft, they typically divide their decision making in a very different way. The StarCraft community typically talks about two tasks:

- *Micro*: is the ability to control units individually (roughly corresponding to *reactive control* above and part of *tactics*). A good *micro* player usually keeps their units alive over a longer period of time.
- *Macro*: is the ability to produce units and to expand at the appropriate times to keep your production of units flowing (roughly corresponding to everything but *reactive control* and part of *tactics* above). A good *macro* player usually has the larger army.

The reader can find a good presentation of task decomposition RTS game AI in Weber et al. (2011a). Although the previous task decomposition is common, other task decompositions have been explored (see Othman et al. (2012) for an overview of the task decomposition used by several StarCraft bots).

Existing Work on RTS Game AI

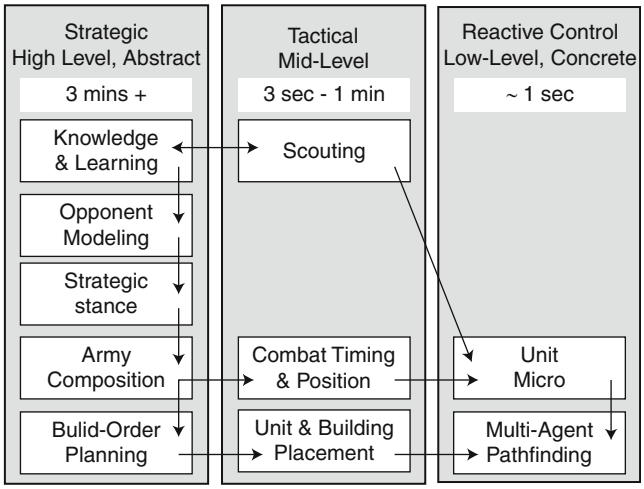
Systems that play RTS games need to address most, if not all, the aforementioned problems together. Therefore, it is hard to classify existing work on RTS AI as addressing the different problems above. For that reason, we will divide it according to three levels of abstraction: strategy (which loosely corresponds to "macro"), tactics, and reactive control (which loosely corresponds to "micro").

Figure 1 illustrates how strategy, tactics, and reactive control are three points in a continuum scale where strategy corresponds to decision-making processes that affect long spans of time (several minutes in the case of StarCraft), reactive control corresponds to low-level second-by-second decisions, and tactics sit in the middle. Also, strategic decisions reason about the whole game at once, whereas tactical or reactive control decisions are localized and affect only specific groups of units. Typically, strategic decisions constrain future tactical decisions, which in turn condition reactive control. Moreover, information gathered while performing reactive control can cause reconsideration of the tactics being employed, which could trigger further strategic reasoning.

The remainder of this section presents work toward addressing the previous six open RTS game AI problems, grouped as work focused toward strategy, tactics, or reactive control, as well as a final section dedicated to holistic approaches that attempt to deal with all three levels at once.

Strategy

In the context of RTS games, high-level strategic reasoning has been addressed using many AI



RTS AI Problems and Techniques, Fig. 1 RTS AI levels of abstraction and typical subproblems associated with them: Timings correspond to an estimate of the duration of a behavior switch in StarCraft

techniques, like hard-coded approaches, planning, or machine learning. We cover each of these approaches in turn.

Hard-Coded Approaches They have been extensively used in commercial RTS games. The most common ones use finite state machines (FSM) (Houlette and Fu 2003) in order to let the AI author hard-code the strategy that the AI will employ. The idea behind FSMs is to decompose the AI behavior into easily manageable states, such as "attacking," "gathering resources," or "repairing," and establish the conditions that trigger transitions between them. Commercial approaches also include hierarchical FSMs, in which FSMs are composed hierarchically. These hard-coded approaches have achieved a significant amount of success and have also been used in many academic RTS AI research systems. However, these hard-coded approaches struggle to encode dynamic, adaptive behaviors and are easily exploitable by adaptive opponents.

Planning Approaches using planning techniques have also been explored in the literature. For example, Ontañón et al. (2008) explored the use of real-time case-based planning (CBP) in the domain of Wargus (a Warcraft II clone). In their work, they used human demonstration to learn plans, which are then composed at run-time in order to form full-fledged strategies to play the game. In Mishra et al. (2008), they improve over their previous CBP approach by using situation assessment for improving the quality and speed of plan retrieval. Hierarchical task network (HTN) planning has also been explored with some success in the context of simpler first-person shooter games (Hoang et al. 2005). Planning approaches offer more adaptivity of the AI strategy compared to hard-coded approaches. However, the real-time constraints of RTS games limit the planning approaches that can be applied, HTN and case-based planning being the only ones explored so far. Moreover, none of these approaches address any timing or scheduling issues, which are key in RTS games. One notable exception is the work of Churchill and Buro (2011), who used planning in order to construct its economic build orders, taking into account timing constraints of the different actions.

Machine Learning Concerning machine learning-based approaches, Weber and Mateas (2009) proposed a data mining approach to strategy prediction and performed supervised learning on labeled StarCraft replays. Dereszynski et al. (2011) used hidden Markov models (HMM) to learn the transition probabilities of sequences of building construction orders and kept the most probable ones to produce probabilistic behavior models (in StarCraft). Synnaeve and Bessiére (2011a) used the dataset of Weber and Mateas (2009) and presented a Bayesian semi-supervised model to

learn from replays and predict openings (early game strategies) from StarCraft replays. The openings are labeled by EM clustering considering appropriate features. Then, in Synnaeve and Bessiére (2011b), they presented an unsupervised learning Bayesian model for tech-tree prediction, still using replays. Finally, evolutionary approaches to determine priorities of high-level tasks were explored by Young and Hawes in their QUORUM system (Young and Hawes 2012), showing improvement over static priorities.

Case-Based Reasoning Also falling into the machine learning category, a significant group of researchers has explored case-based reasoning (CBR) (Aamodt and Plaza 1994) approaches for strategic decision making. For example, Aha et al. (2005) used CBR to perform dynamic plan retrieval in the Wargus domain. Hsieh and Sun (2008) based their work on Aha et al.'s CBR model (Aha et al. 2005) and used StarCraft replays to construct states and building sequences ("build orders"). Schadd et al. (2007) applied a CBR approach to opponent modeling through hierarchically structured models of the opponent behavior, and they applied their work to the Spring RTS game (a "Total Annihilation" clone). Jaidee et al. (2011) study the use of CBR for automatic goal selection while playing an RTS game. These goals will then determine which Q-tables to be used in a reinforcement learning framework. Finally, Čertický et al. (2013) used CBR to build their army, based on the opponent's army composition, and they pointed out on the importance of proper scouting for better results.

Scouting One final consideration concerning strategy is that RTS games are typically partially observable. Games like StarCraft implement the "fog of war" idea, which basically means that a player can only see the areas of the map close to her own units. Areas of the map away from the field of view of individual units are not observable. Players need to scout in order to obtain information about the opponent's strategy. The size of the state space in StarCraft prevents solutions based on POMDPs from being directly applicable, and very few of the previous approaches deal with this problem. Much work in RTS game AI assumes perfect information all the time. For example, in the case of commercial games, most AI implementations cheat, since the AI can see the complete game map at all times, while the human player does not. In order to make the human player believe the AI of these games does not cheat, sometimes they simulate some scouting tasks as Bob Fitch described in his AIIDE 2011 keynote for the WarCraft and StarCraft game series. Even if the StarCraft AI competition enforces fog of war, which means that bots are forced to work under partial information, little published research exists on this topic. A notable exception is the work of Weber et al. (2011b), who used a particle model with a linear trajectory update to track opponent units under fog of war in StarCraft. They also produced tactical goals through reactive planning and goal-driven autonomy (Weber et al. 2010a, b), finding the more relevant goal(s) to spawn in unforeseen situations.

Tactics

We will divide the work on midrange tactical reasoning in RTS games in two large groups: spatial reasoning and decision making (that has been addressed both using machine learning and game tree search).

Spatial Reasoning The most common form of spatial reasoning in the literature of RTS games is terrain analysis. Terrain analysis supplies the AI with structured information about the map. This analysis is usually performed off-line, in order to save CPU time during the game. For example, Pottinger (2000) described the *BANG* engine implemented by Ensemble Studios for the game Age of Empires II. This engine provides terrain analysis functionalities to the game using influence maps and areas with connectivity information. Forbus et al. (2002) showed the importance to have qualitative spatial information for war games, for which they used geometric and path-finding analysis. Hale et al. (2008) presented a 2D geometric navigation mesh generation method from expanding convex regions from seeds. Finally, Perkins (2010) applied Voronoi decomposition (then pruning) to detect regions and

relevant choke points in RTS maps. This approach is implemented for StarCraft in the BWTA (http://eode.google.com/p/bwta/) library, used by most state of the art StarCraft bots.

Another form of spatial reasoning that has been studied in RTS games is *walling*. Walling is the act of intentionally placing buildings at the entrance of your base to block the path and to prevent the opponent's units from getting inside. This technique is used by human StarCraft players to survive early aggression and earn time to train more units. Čertický addressed this constraint satisfaction problem using answer set programming (ASP) (Čertický 2013). Richoux et al. (2014) presented an alternative approach based on constraint programming and local search, designed to be run-time.

Machine Learning Concerning tactical decision making, many different approaches have been explored such as machine learning or game tree search. Hladky and Bulitko (2008) benchmarked hidden semi-Markov models (HSMM) and particle filters for unit tracking. Although they used first-person shooter (FPS) games for their experimentation, the results apply to RTS games as well. They showed that the accuracy of occupancy maps was improved using movement models (learned from the player behavior) in HSMM. Kabanza et al. (2010) improve the probabilistic hostile agent task tracker (PHATT (Geib and Goldman 2009), a simulated HMM for plan recognition) by encoding strategies as HTN, used for plan and intent recognition to find tactical opportunities. Sharma et al. (2007) combined CBR and reinforcement learning to enable reuse of tactical plan components. Cadena and Garrido (2011) used fuzzy CBR (fuzzy case matching) for strategic and tactical planning. Synnaeve and Bessière (2012b) combined space abstraction into regions from Perkins (2010) and tactical decision making by assigning scores (economical, defenses, etc.) to regions and looking for their correspondences to tactical moves (attacks) in pro-gamer replays. Finally, Miles and Louis (2006) created the idea of *IMTrees*, a tree where each leaf node is an influence map, and each intermediate node is a combination operation (sum, multiplication); Miles used evolutionary algorithms to learn IMTrees for each strategic decision in the game involving spatial reasoning by combining a set of basic influence maps.

Game Tree Search These techniques have also been explored for tactical decision making. Churchill et al. (2012a) presented the ABCD algorithm (Alpha-Beta Considering Durations), a game tree search algorithm for tactical battles in RTS games. Chung et al. (2005) applied Monte Carlo planning to a capture-the-flag version of Open RTS. Balla and Fern (2009) applied the UCT algorithm (a Monte Carlo Tree Search algorithm) to tactical assault planning in Wargus. To make game tree search applicable at this level, abstract game state representations are used in order to reduce the complexity. Uriarte and Ontañón (2014) explored different game state abstractions in the context of Monte Carlo Tree Search for high-level tactical reasoning in StarCraft. Other algorithms, such as Greedy Portfolio Search (Churchill et al. 2012a), perform abstraction at the level of actions, by employing a collection of predefined "scripts" and using these scripts as the possible actions that the players can execute in the context of game tree search.

Reactive Control

Reactive control has been addressed mainly via the application of potential fields or by using machine learning to learn good control policies. We also include work on pathfinding as part of reactive control.

Potential Fields Potential fields and influence maps have been found to be useful techniques for reactive decision making. Some uses of potential fields in RTS games are avoiding obstacles (navigation), avoiding opponent fire (Uriarte and Ontañón 2012), or staying at maximum shooting distance (Hagelbäck and Johansson 2009). Potential fields have also been combined with A* pathfinding to avoid local traps (Hagelbäck 2012). Hagelbäck and Johansson (2008) presented a multi-agent potential field-based bot able to deal with fog of war in the Tankbattle game. Avery et al. (2009) and Smith et al. (2010) coevolved

influence map trees for spatial reasoning in RTS games. Danielsiek et al. (2008) used influence maps to achieve intelligent squad movement to flank the opponent in an RTS game. Despite their success, a drawback for potential field-based techniques is the large number of parameters that has to be tuned in order to achieve the desired behavior. Approaches for automatically learning such parameters have been explored, for example, using reinforcement learning (Liu and Li 2008) or self-organizing maps (SOM) (Preuss et al. 2010). We would like to note that potential fields are a reactive control technique, and, as such, they do not perform any form of lookahead. As a consequence, these techniques are prone to make units stuck in local optima.

Machine Learning There has been a significant amount of work on using machine learning techniques for the problem of reactive control. Bayesian modeling has been applied to inverse fusion of the sensory inputs of the units (Synnaeve and Bessiere 2011c), which subsumes potential fields, allowing for integration of tactical goals directly in micromanagement.

Additionally, there have been some interesting uses of reinforcement learning (RL) (Sutton and Barto 1998): Wender and Watson (2012) evaluated the different major RL algorithms for (decentralized) micromanagement, which perform all equally. Marthi et al. (2005) employ concurrent hierarchical Q-learning (units' Q-functions are combined at the group level) RL to efficiently control units in a "one robot with multiple effectors" fashion. Madeira et al. (2006) advocate the use of prior domain knowledge to allow faster RL learning and applied their work on a turn-based strategy game. This is because the action space to explore is gigantic for real game setups. It requires exploiting the existing structure of the game in a partial program (or a partial Markov decision process) and a shape function (or a heuristic) (Marthi et al. 2005). Another approach has been proposed by Jaide and Muñoz-Avila (2012) through learning just one Q-function for each unit type, in order to cut down the search space. Other approaches that aim at learning the parameters of an underlying model have also been explored. For example, Ponsen and Spronck (2004) used evolutionary learning techniques, but face the same problem of dimensionality. For example, evolutionary optimization by simulating fights can easily be adapted to any parameter-dependent micromanagement control model, as shown by Othman et al. (2012) which optimizes an AIIDE 2010 micromanagement competition bot.

Finally, approaches based on game tree search are recently being explored for micromanagement. Churchill et al. (2012b) presented a variant of alpha-beta search capable of dealing with simultaneous moves and durative actions, which could handle reactive control for situations with up to eight versus eight units.

Other research falling into reactive control has been performed in the field of cognitive science, where Wintermute et al. (2007) have explored humanlike attention models (with units grouping and vision of a unique screen location) for reactive control.

Pathfinding Finally, although pathfinding does not fall under our previous definition of reactive control, we include it in this section, since it is typically performed as a low-level service, not part of either tactical or strategical reasoning (although there are some exceptions, like the tactical pathfinding of Danielsiek et al. (2008)). The most common pathfinding algorithm is A*, but its big problem is CPU time and memory consumption, hard to satisfy in a complex, dynamic, real-time environment with large numbers of units. Even if specialized algorithms, such as D*-Lite (Koenig and Likhachev 2002) exist, it is most common to use A* combined with a map simplification technique that generates a simpler navigation graph to be used for pathfinding. An example of such technique is Triangulation Reduction A* that computes polygonal triangulations on a grid-based map (Demyen and Buro et al. 2006). Considering movement for groups of units, rather than individual units, techniques such as steering of flocking behaviors (Reynolds 1999) can be used on top of a pathfinding algorithm in order to make whole groups of units follow a given path. In recent commercial RTS games like StarCraft 2 or Supreme Commander 2, flocking-like behaviors are inspired of

continuum crowds ("flow field") (Treuille et al. 2006). A comprehensive review about (grid-based) pathfinding was recently done by Sturtevant (2012).

Holistic Approaches

Finally, holistic approaches to address RTS AI attempt to address the whole problem using a single unified method. To the best of our knowledge, with a few exceptions, such as the Darmok system (Ontañón et al. 2010) (which uses a combination of case-based reasoning and learning from demonstration) or ALisp (Marthi et al. 2005), there has not been much work in this direction. The main reason is that the complexity of RTS games is too large, and approaches that decompose the problem into smaller, separate problems achieve better results in practice. However, holistic approaches, based, for example, on Monte Carlo Tree Search, have only been explored in the context of smaller-scale RTS games (Ontañón 2013). Techniques that scale up to large RTS games as StarCraft are still not available.

A related problem is that of integrating reasoning at multiple levels of abstraction. Molineaux et al. (2008) showed that the difficulty of working with multi-scale goals and plans can be handled directly by case-based reasoning (CBR), via an integrated RL/CBR algorithm using continuous models. Reactive planning (Weber et al. 2010b), a decompositional planning similar to hierarchical task networks (Hoang et al. 2005), allows for plans to be changed at different granularity levels and so for multi-scale (hierarchical) goal integration of low-level control. Synnaeve and Bessière (2011c) achieve hierarchical goal (coming from tactical decisions) integration through the addition of another sensory input corresponding to the goal's objective.

Conclusions

This entry has defined real-time strategy (RTS) games from an AI point of view and summarized the set of open problems in RTS game AI. After that, we have summarized existing work toward addressing those problems.

RTS games can be seen as a simulation of real complex dynamic environments, in a finite and smaller world, but still complex enough to study a series of key interesting problems. Finding efficient techniques for tackling these problems on RTS games can thus benefit other AI disciplines and application domains and also have concrete and direct applications in the ever-growing industry of video games.

Information visualization; Scalable techniques; Spatiotemporal data

Definition

Spatiotemporal visualization uses a set of tools and techniques to explore and explain changes of information in space and time, aiming to convey specific insights in large and complex data sets to humans (Zhong et al. 2012).

Introduction

Our world is saturated with spatiotemporal data. Spatiotemporal visualization plays an important role in the discovery and understanding of the inherent nature of data. Zhong et al. (2012) defined spatiotemporal visualization as a set of tools and techniques to explore changes of information in space and time, aiming to convey specific insights in large and complex data sets to humans. Researchers have created numerous applications and techniques to visualize spatiotemporal data as efficiently and effectively as possible. Space-time cube (Gatalsky et al. 2004), small multiples (Tufte 2001), the choropleth map (Nöllenburg 2007), and stacked area charts (Hao et al. 2005) were proposed to represent spatiotemporal phenomena. The scalability in information visualization has been a big challenge to visualize large-scale spatiotemporal data sets. Cook and Thomas (2005) listed five major scale issues that were related to visual analytics: information scalability, visual scalability, display scalability, human scalability, and software scalability. This entry will summarize the techniques that were used to visualize spatiotemporal data from the five perspectives.

A case study will be demonstrated with 2014 VAST Mini-challenge 2 dataset. Researchers designed a polygon-based visualization to display large GPS tracking data at different levels of time series.

State-of-the-Art Work

Information Scalability

Cook and Thomas (2005) defined information scalability as the capability to extract relevant information from massive data streams, the capability to handle dynamic change, and the capability to be scaled to the target audience.

One of information scalability tasks is to filter the data and show only the most relevant data (Robertson et al. 2009). Information scalability requires the representations of data at multiple levels of abstraction and scales. Data abstraction is able to reduce the number of items to display in data space. It attempts to hide away details without losing the essential meaning. The standard data abstraction technique is dimension reduction, whose strategies include principal component analysis, factor analysis, multidimensional scaling, subsetting, segmentation, and aggregation.

Information scalability also needs to deal with a wide range of dynamic change. The common approach is the autoregressive integrated moving average (ARIMA) methodology (Box et al. 2008). The model examines the relationships of variables over time and helps to understand the events and predict future points in the series. More recent research has focused on mining multivariate time series data. Minnen et al. (2007) proposed an algorithm to locate regions of high density in the space of all time-series subsequences to discover multivariate motifs. Wang and Willett (2004) presented a computationally efficient solution to solve the joint segmentation and classification of a time series. Some work has investigated the design of system architecture. Lian et al. (2008) proposed the pattern-matching problem over high dimensional cloaked series. The researchers indexed the cloaked time series and proposed an efficient approach to answering the cloaked range query. Besides that, distributed data streams Bandyopadhyay et al. (2006) were presented to deal with high-dimensionality streaming data. The key to the technique was the online micro-clusters that could be extracted over the required period.

Visual Scalability

Visual Scalability is the capability of visualization representation and visualization tools to display massive datasets effectively, regarding either the number or the dimension of the individual data element (Eick and Karr 2002). According to Cook and Thomas (2005), factors affecting visual scalability include the quality of visual displays, the visual metaphors used in the display of information, the techniques used to interact with the visual representations, and the perception capabilities of the human cognitive system.

A screen contains millions of pixels. Researchers cannot use all the pixels to display data elements because it is impossible for the audience to perceive them. Thus, the number of perceivable pixels and data elements that can be displayed is limited. Robertson et al. (2009) proposed that the fundamental problem of visual scalability was how to visually represent a very large number of data elements in a much smaller number of visual display elements so that the user's task could be performed. Visual scalability aims to handle huge amounts of data and display the large-scale relationship with an overview. Researchers have explored innovative ways of displaying large-scale spatiotemporal data. The approaches can be classified as geometric projections, pixel-oriented views, and hierarchical presentations.

Geometric Projections

This technique aims at finding informative projections and transformations of multidimensional datasets (Keim and Kriegel 1996). Analytics can map the attributes to a Cartesian plane like scatterplot or an arbitrary space like parallel coordinates. Tominski et al. (2012) introduced a novel stacking-based technique to facilitate gaining insights into trajectory attribute data. With a combination of 2D map and stacked 3D trajectory bands, the approach was able to display more

than 10 billion position records and 14,000 trajectories in total. To mitigate the clutter issue, recent researchers have proposed density-based approaches to visualize a lot of data points.

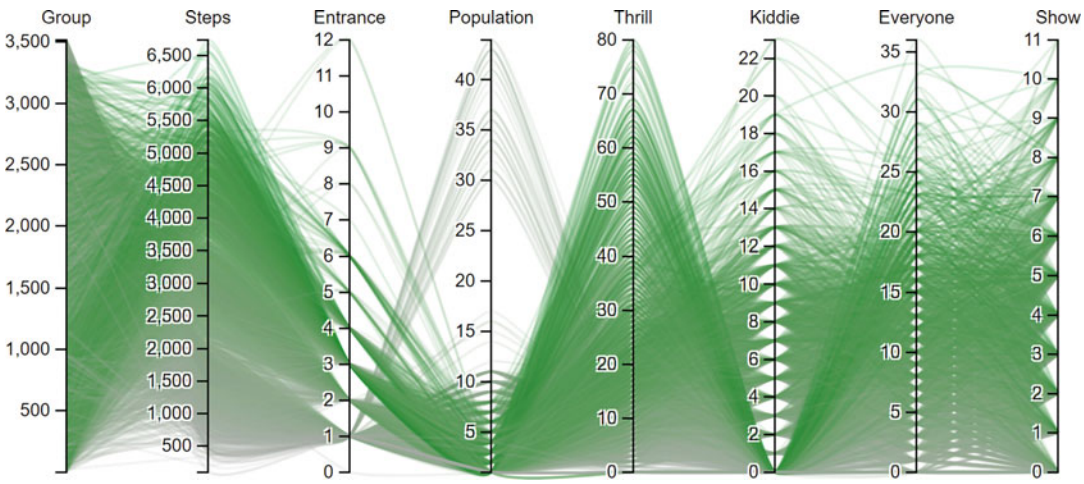
Wei et al. (2015) used data binding to detect outlier and generate context to parallel coordinates. The system was able to handle datasets of up to 25 million records (Fig. 1).

Pixel-Oriented Visualization

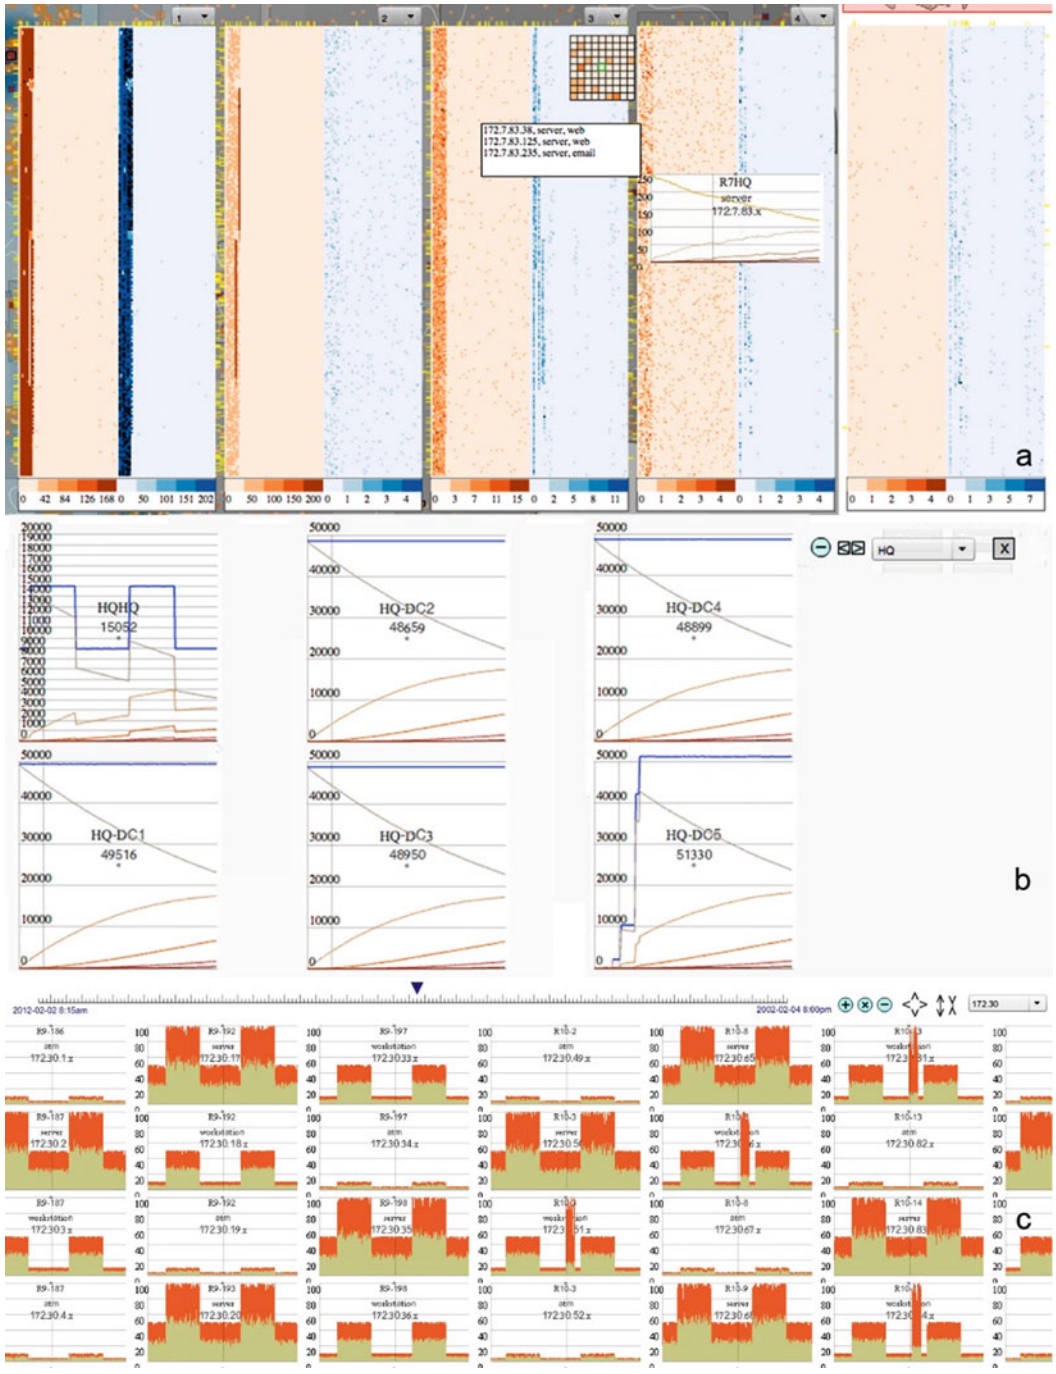
Pixel-oriented visualization aims at representing as many data records as possible on the screen by mapping each value to a colored pixel and arranging the data values based on the inherent ordering of data objects within the separated sub-window (Keim 2000). The early approaches of pixel-oriented visualization include high information density displays like Eick's SeeSoft that allowed users to analyze up to 50,000 lines of code simultaneously by mapping each line of code into a thin row for finding interesting patterns (Eick et al. 1992). Scheepens et al. (2011) presented an interactive approach to visualize trajectories with multiple attributes using density maps. Density maps can be used to display more than three million data points with a density field of 1250 × 1020 cells on a screen of 900 × 900 pixels. Chen et al. (2015) presented cyber security datasets, which contained millions of computers on the pixel-oriented visualization. The IP block pixel-based visualization had three levels. Mouse over Fig. 2a can see enlarged pixels. Clicking a pixel would evoke the corresponding time series curves of the pixel on Fig. 2b. Users are able to notice abnormal patterns in Fig. 2b. Clicking on one curve would evoke more detailed information presenting on Fig. 2c.

Hierarchical Presentations

Hierarchical presentations include treemaps, dimensional stacking, star glyph, and texture. The hierarchical techniques subdivide the k-dimensional space and present the subspaces in a hierarchical fashion (Keim and Kriegel 1996). Dimensional stacking technique is widely used for the visualization of multiple time series data. ThemeRiver was a novel visualization method to represent thematic variations over time where the layers were stacked in a symmetrical shape along the x-axis (Havre et al. 2000).



Scalable Techniques to Visualize Spatiotemporal Data, Fig. 1 The parallel coordinate with eight dimensions presents 25 million movement records within an amusement park (Reprinted from Wei et al. 2015). In sequence, the dimensions are group index of visitors, visitors' walking steps within the park, the times of entering the park, the population of the group, the taking number of thrill rides, the taking number of kiddie rides, the taking number of everyone rides, and the taking number of show rides. With interaction, outliers can be detected accurately



Scalable Techniques to Visualize Spatiotemporal Data, Fig. 2 Pixel-based visualization of IP blocks (Reprinted from Chen et al. 2015). **(a)** Each pixel represents a group of computers, **(b)** the curves of policy statuses, activities, or the number of connections curves of the selected pixel, and **(c)** zoom in to show the detailed graphs of the number of connections

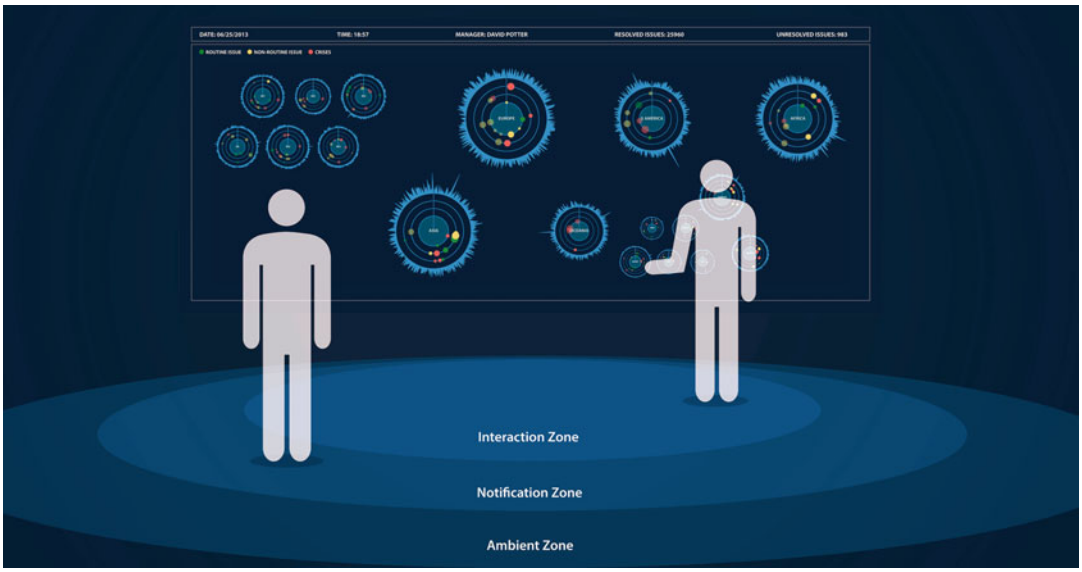
The NameVoyager used a set of interactive and color-coded stacked graphs to visualize hierarchical time series. It enabled users to explore a set of 6000-time series (Wattenberg and Kriss 2006). Wongsuphasawat et al. (2011) used colored triangles on a horizontal timeline to analyze large numbers of event sequences. In LifeFlow, more than two million incidents could be displayed to support users' exploration. However, stacked graphs may mislead audiences because the boundaries of each layer lie in the continuous curving lines. The varying baseline of the layout will also make the overall graph much harder to read.

Beside typical hierarchical presentation, researchers also proposed some novel hierarchical interactions. As is shown in Fig. 3, SolarWheel (Chang et al. 2013) allowed multiple analysts to interact with the display. Different hierarchy levels would be present according to the analysts' distance to the display. The combination of hierarchical structure and interaction, the display can present millions of data according to the requirements of analysts.

Display Scalability

According to Cook and Thomas (2005), most visualization systems only fit the common desktop display (1280 × 1024 pixels). It is important to develop techniques that scale to various display such as a wall-sized display, a PDA, or a phone-sized display. Cook and Thomas (2005) stated that the major challenge was to develop interaction techniques that were displayed scale-independent, particularly on small displays.

Rønne Jakobsen and Hornbæk (2011) designed a controlled experiment to compare three classic interactive visualization techniques – focus + context, overview + detail, and zooming with varying display size (13.8, 1.5, and 0.17 megapixels). The results showed that overview + detail worked best across different display sizes, while focus + context was more difficult to use at a small display size. As a display-scale independence design, FacetMap used a space-filling metaphor to allow users to browse and search for facet values (Smith et al. 2006). FacetMap was able to work on any size display and adapted its



Scalable Techniques to Visualize Spatiotemporal Data, Fig. 3 The display monitor will detect the sight direct and the standing distance of analysts to decide the stats of Solar Wheels (Reprinted from Chang et al. 2013). When an analyst is in the ambient zone, the highest level of the hierarchy will be present to give an overview. When analyst goes into notification zone or interaction zone, the Solar Wheels will split into small wheels to show the lower level, the volume of data will be depicted to analysts

information layout to reveal more information with larger displays. However, because displaying information on the phone-sized screen required too many effective interactions, FacetMap needs more effort to get down to small displays. Many existing techniques are usually limited to explore large data items using mobile and handheld computers such as personal digital assistants (PDAs) or subnotebooks. Many researchers have tended to adopt a second approach that is to use the small screen as a window onto a larger virtual space (Gutwin and Fedak 2004). Gutwin and Fedak (2004) compared three techniques for using large interfaces on small screens: a panning system similar to what was in current use, a two-level zoom system, and a fisheye view. They tested these techniques with three realistic tasks and found that people performed faster with the fisheye view, that the two-level zoom was significantly better for a monitoring task, and that people were slowest with the panning system.

SpringRain (Promann et al. 2013) combined display with Google Glass to present overview and detail information for users (Fig. 4b). The overview presentation can be applied to varying display sizes such as wall-size or computer monitor size (Fig. 4a).

Human Scalability

Cook and Thomas (2005) reported that human skills and abilities were fixed and did not scale, but the number of humans involved in analytical problem-solving and response activities did scale. Researchers should develop techniques that scale from a single user to a collaborative environment. Users may be collaborating from within the same team in an organization, at different levels of an organization, or even in different organizations.

Geocollaboration is regarded as the use of a visual display by two or more participants to frame and address a problem or to complete a task (MacEachren 2001). Schafer et al. (2007) developed a geocollaboration tool to support community-wide emergency management planning and preparedness. The software architecture was beneficial to the design and implementation of geocollaboration applications. Issues such as emergency vehicle traffic routes and staging areas for command posts, arriving media, and personal first responders' vehicles can be examined together and collaboratively through the software. Besides situations like crisis management and building planning, geocollaborative tasks can also support a situated learning activity to train students in acquiring IT skills. Baloian and Zurita (2016) proposed a geocollaborative application including georeferencing and microblogging-like messages to support the pedagogical activity. The evaluation provided positive results for the geocollaborative application and offered valuable insights on the implementation of a collaborative visualization system to support learning activities for large groups.

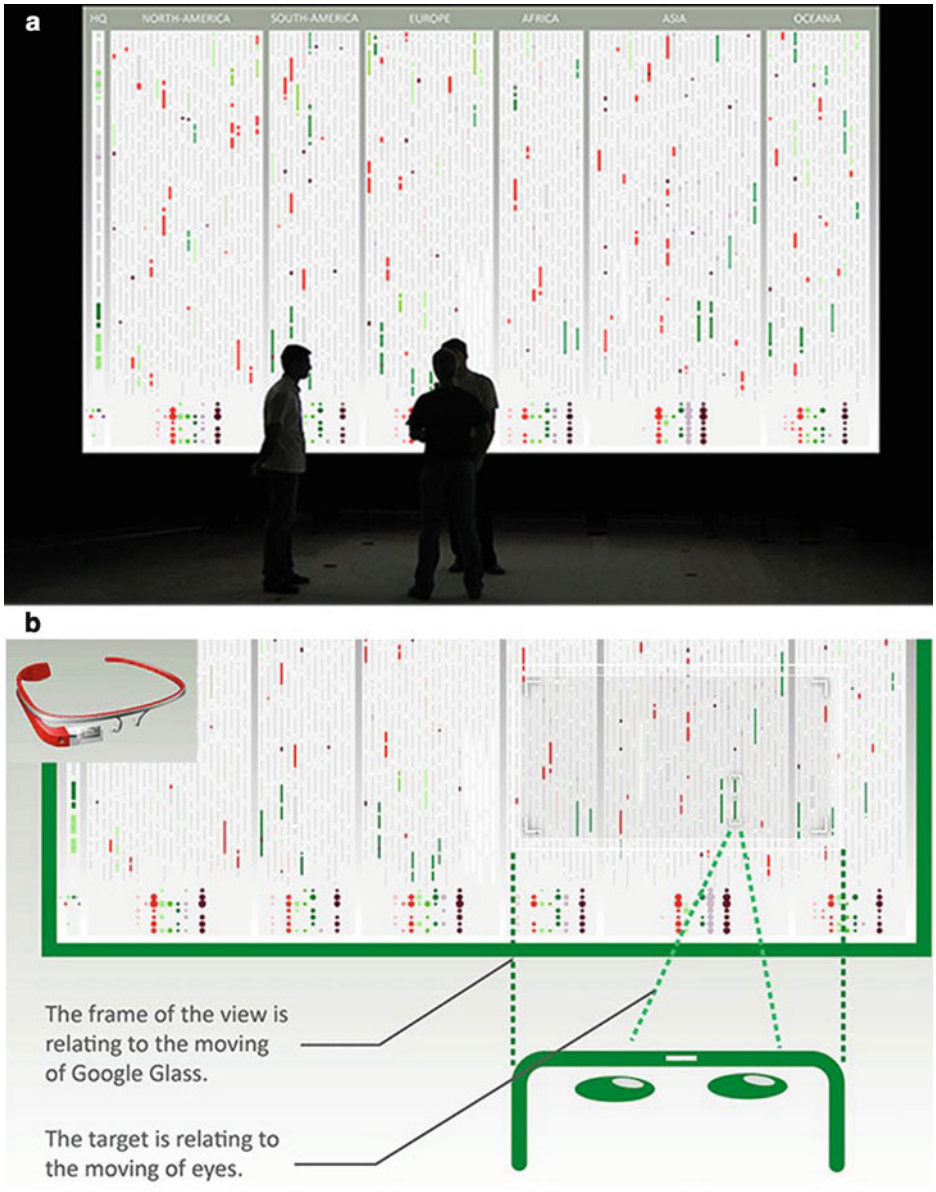
Software Scalability

The capability of software systems to be configured to interactively manipulate data sets of various sizes is called software scalability (Cook and Thomas 2005). This includes the generation of new algorithms that scale to the ever-increasing generated information sets.

WiGis was able to support user interactions with large graphs in a web browser without the need for plug-ins or special-purpose runtime systems (Gretarsson et al. 2010). The researchers found that the main scalability limitation was because most of the systems implemented some form of a thick client solution and subsequently needed to load the entire graph onto the client machine. WiGis circumvented these limitations by leveraging a novel technique for storing and processing graph data on a powerful remote server. To achieve fast processing, Zinsmaier et al. (2012) extended Kernel Density Estimation (KDE) for node aggregation by a two-pass seed point rendering. This technique significantly reduced geometry and scaled to large graph with millions of nodes and edges.

Case Study: A Polygon-Based Visualization Approach to Display Large GPS Tracking Data

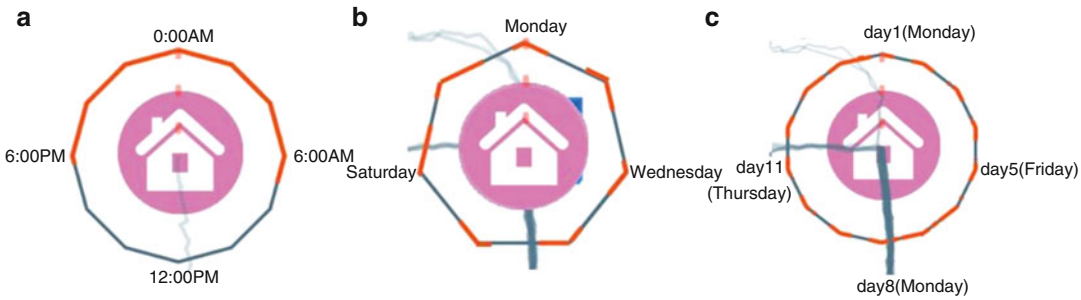
This section demonstrates our design concept that can be used to visualize human life patterns from a



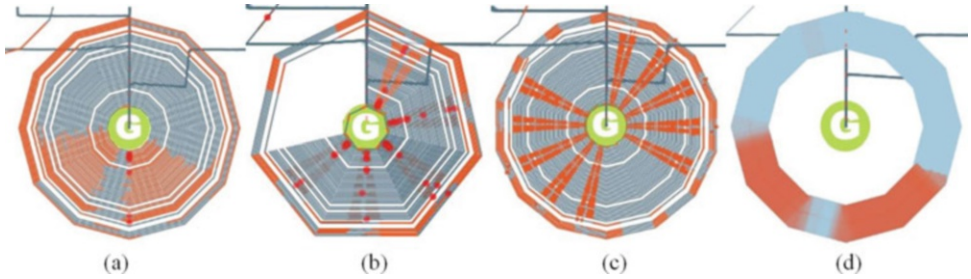
Scalable Techniques to Visualize Spatiotemporal Data, Fig. 4 (**a**) the SpringRain is applied to the wall-size display. (**b**) Google Glass shows detail information according to the moving of glasses and eyes (Reprinted from Promann et al. 2013)

large GPS tracking data set. The system won an award in VAST Challenge 2014 (Guo et al. 2014). 2014 VAST Mini-challenge 2 data are used to study daily routines because the simulation data contain timestamp, latitude, and longitude and show high fidelity on spatial and temporal attributes. The dataset contains 70 million GPS records, 1500 credit card transactions, and 1400 loyalty card transactions for 40 cars during 2 weeks.

Researchers designed n-side regular polygons on a map to visualize time and geographical locations of GPS data within a single view. Polygons with different sides are able to show different



Scalable Techniques to Visualize Spatiotemporal Data, Fig. 5 (**a**) One dodecagon shows one subject's daily activities at home. This subject stays at home from about 6 pm to 7 am. (**b**) One heptagon denotes one subject's weekly activities at home. Audiences can tell that this subject frequently arrives at home before midnight and leaves home in the morning. He stays at home most of the time during the weekends. (**c**) One 14-sided polygon represents one subject's activities during 2 weeks. It is enough to show this subject's weekly routine. This subject leaves at home early in the morning, goes back home directly after work, takes a short rest, and goes outside. He usually returns home before midnight



Scalable Techniques to Visualize Spatiotemporal Data, Fig. 6 (**a**) Nested dodecagons to show subjects' activities at the company in 1 day. (**b**) Nested heptagons to show subjects' daily activities at the company in 1 week. (**c**) Nested 14-sided polygons to show subjects' weekly activities at the company during 2 weeks. (**d**) One thick ring with color shades to show the frequency of stay regarding a large number of subjects

periods. Each side of a polygon can represent 1 day, 1 week, 1 month, or 1 year. As is shown in Fig. 5a, one dodecagon can represent 1 day with each side denoting 2 h. The orange segment marked on the dodecagon corresponds to the periods of stay. Figure 5a shows that the subject goes back home at around 6 pm and leaves home at around 7 am. A home logo is placed in the center of the dodecagon as a point of interest. One heptagon is suitable to show subjects' weekly routine, and the orange segments reveal start and end times as well as the time range of home stay (Fig. 5b). A 14-sided polygon is drawn to display the subject's daily activities during 2 weeks (Fig. 5c). Figure 5c shows that the subject frequently comes home after work and then goes out for dinner. He usually returns home before midnight and leaves home in the morning. Thus, the polygon-based visualization flexibility displays periodic time series and can be scaled to visualize large volumes of time series data.

Regarding a large number of subjects, polygons can be nested together on a map to present a set of subjects and reveal events occurring while the subjects occupy places at times. Figure 6 shows 40 subjects' activities occurring at the company. Each polygon represents one subject. Nested polygons from inside to outside denote subjects from the first to the 40th. There is a company logo in the middle of the concentric polygons, which presents the location type. The orange segment corresponds to the stay range, and the red dot on a segment represents a credit card transaction.

Figure 6a shows the subjects' 24-hour activities at the company. Nested dodecagons tell us

that most of the subjects go to work at around 8 am, leave the office for lunch, return to work at around 2 pm, and leave the office at around 6 pm. Audiences can also see that several subjects spent some money around noon based on the position of red dots. Figure 6b displays subjects' daily routine in 1 week. Nested heptagons show that most of the subjects go to work during the weekdays and leave office during the weekends. A few subjects stay at the company during the night and leave it in the afternoon. The weekly life pattern is also very clear in the 14-sided concentric polygons for 2-weeks' data (Fig. 6c). To cope with large datasets, a thick polygon is designed to scale the data to visualize a large number of subjects without overlapping or visual cluttering. As is shown in Fig. 6d, the graph uses one thick ring instead of nesting dodecagons to show subjects. The stay range with the highest density determines the thickness of the ring. Color shades on the ring correspond to the percentage of stay range. Deeper yellow colors denote more frequent stays, and lighter yellow colors represent shorter stay periods in 1 day. Thus, the visualization can show an overview of many subjects with aggregation for a certain period.

In this study, researchers use polygon as the main metaphor to record subjects' temporal activities during different periods. Nested polygons on a map can present a large number of subjects' routine. With the polygon-oriented glyph design, analysts can view regions of interest at different levels of periodic time series.

Conclusion

This entry provides a detailed overview of the current scalable spatiotemporal visualization techniques from the perspectives of information scalability, visual scalability, display scalability, human scalability, and software scalability. A case study demonstrates how a polygon-based visualization is used to display a large number of GPS tracking data. However, a big limitation of the design is that the inner polygons are smaller than the outer ones and it may not be easy for audiences to discern information from small polygons. With massive amounts of information drawn on polygons, a thick ring can only show the overview of temporal patterns while losing the details of individual activities. Authors admit that the presented concept in this entry is simple and easy to implement. This entry does not introduce new visual approaches to encode time series data. Our idea is just to provide a flexible and consistent way to display different levels of time series with a variety of different visualizations. The drawing metaphor is intuitive to audiences, and the method is very easy to use. Integrating the visualization method with GPS tracking data would empower the analysis of human life patterns of sparsely sampled data.

Secure Gaming: Cheat-Resistant Protocols and Game History Validation

Ferdinand Schober
Xbox Advanced Technology Group, Microsoft Corporation, Redmond, WA, USA

Synonyms

Anti-cheat protocols; Cheat-resistant gaming; Game integrity validation; Game state validation

Definition

Cheat-resistant protocols and game history validation are design approaches to limit and reduce cheating in massively multiplayer online (MMO) or multiplayer games. Cheat-resistant protocols follow design principles that reduce or eliminate cheating through alteration of game communication. Game history validation is a method to ensure the integrity and consistency of dynamic and static game state to identify and correct cheating attempts.

Motivation

In forums, MMOs, and multiplayer games, it is common to find stories about cheaters and the issues they cause. Posts describe how other players have impossibly powerful characters, seemingly ignore game rules, or quit a game right before a loss without penalty. Excessive cheating can cause players to avoid an otherwise fun game and result in severe losses for game developers and publishers.

Cheating is not a recent phenomenon, cheating in games has an equally long history as online gaming itself: one of the first peer-to-peer networked multiplayer games, Maze War, was released in 1975 and soon after its release altered clients were available that provided a god-like view to make all other players visible.

Gaming has drastically changed and matured since then. Online games and MMOs are more popular than ever (Valve 2015). E-sports and in-game economies are increasingly backed by real money and require robust security and cheat detection. Now multiplayer and MMO game design is at a stage where game developers are no longer investigating *how* to build these games, but rather how to build them *more securely and efficiently.*

Any competitive multiplayer game needs to be built from the ground up to resist cheating. This entry will illustrate the general principles for cheat-resistant protocol design and then show how to build a secure peer-to-peer protocol that provides strong cheat resistance even if malicious players are present.

Background: Cheat Taxonomy

Cheating can be defined as "the action of pretending to obey the rules of the game, while secretly subverting them to gain advantage over an opponent" (Thompson 2007). Cheating therefore covers a wide area of possible attacks, both technical and nontechnical, and it is important to understand possible attack paths before creating defenses against them:

1. **Active game state attacks**
   Instead of passively exploiting game logic, active attacks change game state outside of game logic either by altering game data (stored on disc or in memory), executables, or communication. Examples of active game state attacks are: save game editors that change stored game state on disc, game trainers that alter game state in memory, wall hacks that reveal hidden players, or traffic shaping tools that allow to alter selective network communication (Hoglund and McGraw 2008; Table 1).
2. **Passive game exploits**
   These attacks are against game logic or game flow and exploit missing limits or bugs to benefit the attacker. Instead of breaking outside of the game rules, the cheater primarily stays within the system to gain an advantage. Examples of passive exploits are: game design exploits like repeatability of a highly rewarding game objective, timing glitches that allow for in-game item duplication, or benefits from service disconnection. These types of exploits can often be addressed through gameplay design changes or code bug fixes and will not be covered in detail here (Table 2).

To provide perfect cheat resistance, defenses against all of the previously mentioned attacks and exploits are needed.

Background: Existing Solutions

Nearly all attacks in online games are more effective when the cheater is also the host of the

Secure Gaming: Cheat-Resistant Protocols and Game History Validation, Fig. 1 Concurrent player count (*solid line*) vs. server allocation (*dotted line*) – with a single datacenter, overallocation of servers is needed. Best fitting available server resources to the player curve requires constant tweaking and initial overallocation. In contrast, the cloud can be fit tightly to the player curve

gameplay simulation. Therefore, most games either limit or prevent cheaters from hosting either by randomizing peer hosting or using dedicated game servers (Aldridge 2011; Weilbacher 2012).

Randomized peer hosting does not prevent a cheating host, but it aims to reduce the probability of a cheater as host. It does so by randomizing host selection. Instead of matching the host predictably (e.g., the first player or the player with the best network connection), multiple host candidates are identified and a random host is then selected from the candidates. This added complexity can eliminate automated cheating attempts, but it is often possible for a more sophisticated attacker to manipulate the candidate selection through traffic shaping (e.g., eliminating other host candidates through filtering).

To avoid peer hosting issues altogether, game developers and publishers often choose to focus on closed console platforms and host servers in datacenters. This approach limits the attack vector of cheaters and provides increased security over peer-to-peer gameplay by putting most of the game logic into a controlled environment. It allows full, ongoing game state control and monitoring. For this approach, the client is often only a viewport into the state of the dedicated server. The less logic a client is responsible for, the more cheat resistant this design is.

However, game servers require significant ongoing financial investment. Single datacenter hosting has to exceed concurrent player numbers (Fig. 1) and can cause scalability bottleneck when player numbers spike.

To limit cost impact, developers and publishers increasingly turn to cloud services to host game servers (Shiring 2013). Adding and removing cloud servers is less costly and server resources can be fitted more tightly to concurrent player counts. Cloud services are also able to absorb unexpected usage spikes during the lifetime of a game more easily than dedicated datacenters.

Despite these benefits, cloud hosting is not a perfect solution for all games. Cloud servers still have ongoing operational cost that can be prohibitive for smaller games and studios. In addition, server-based games have a very finite lifespan: when servers are shut down, the game is not playable anymore. This hard sunset can often alienate even the most dedicated players.

The following design shows an alternative to cloud hosting by building a peer protocol that provides similar security and cheat resistance but with minimal server costs.

Secure Gaming Design Basics

When designing a new system, it is best to start by determining which security and anti-cheating guarantees that are needed. Independent of game type or game mode, the following guarantees are essential for any cheat-resistant design:

1. *Strong player identities*
   Players should not be able to participate in multiplayer gameplay without presenting a strong proof of identity. Such identities should be a scarce resource and costly to replace. Strong identities can be used to uniquely identify cheaters and punish them if needed.
2. *Message integrity and authenticity*
   Any type of message between players needs to be protected from modification and replay attacks. Furthermore, message authenticity has to be verifiable. Without these guarantees, cheaters can assume other identities and manipulate messages of players and services. For most games, message confidentiality is also essential to cheat-resistant game play.
3. *Limited information*
   Any nonpublic game state should only be shared with game clients that need it for logic purposes. This eliminates the possibility for cheating players to assemble a full game state view and observe actions that should be hidden (wall hacks).
4. *Gameplay verifiability*
   Gameplay actions need to be verifiable. Given a set of starting conditions and game actions, a game client should be able to determine if all game actions were valid and which final outcome is expected. Verifiable gameplay allows the identification of current and past cheating attempts.

A system that provides these guarantees can provide cheat-resistant gameplay. Guarantee 1 and 2 can be implemented directly through general-purpose security solutions. Guarantee 3 is more complex: the flow of game state between players needs to be closely examined and any unnecessary/unobservable information should be removed. This impacts the complexity of the game engine and reduces latency tolerance but it greatly decreases possible cheat vectors.

Guarantee 4 is essential for any type of cheat detection, specifically in a peer-to-peer model without a secure server host. In this model, clients need to be able to verify the actions of other untrusted peers. How to achieve this is not immediately obvious: by definition, a peer-to-peer network has no single arbiter. It may therefore seem futile to even attempt to create a cheat-resistant peer-to-peer system.

However, when looking at games, the vast majority of players will fall into one of the three categories:

1. Casual players that are participating in a friendly game with their friends. These players are highly unlikely to cheat due to the casual nature of their gameplay.
2. Competitive players that see the game as a challenge. These players rarely consider cheating since it would detract from the challenge of the game.
3. Opportunistic cheaters that will use exploits or cheats only if they are easy and risk-free (e.g., item-duplication glitches). These players generally do not actively participate in cheating.

Only a tiny fraction of players will attempt active cheating through active game state attacks. In other words, when looking at a larger sample set of players, the *honest* players will be the majority. This insight can be used to build a protocol that uses game simulation results of the combined player base to reach a consensus through voting.

In voting a system, multiple untrusted components perform the same computational operations and each component "votes" with its computational result. The result with the majority of votes becomes the global consensus result of the system. This approach is used in redundant fault-tolerance to identify processing errors for critical systems like aviation control (Lyons and Vanderkulk 1962). The underlying assumption in these systems is that the error results (similar to cheating players) only occur rarely.

The same principle can be applied to cheat detection as well. Assume that any given player is a cheating player with a probability of $\frac{1}{c}$, which (as noted before) is rather small for most games. When looking at a group of n players, the chance of picking a group that consists of only cheaters is $\left(\frac{1}{c}\right)^n$. For large n and c, the probability of having a group of cheaters decreases therefore quickly. A vote in a large group of players should be dominated by honest players and cheaters should be the minority. To be more precise, the probability p that $\frac{1}{x}$ of the players in a group of n are cheaters is $p = \left(\frac{1}{c}\right)^{n/x}$. This probability is critical: it has to be low to ensure an honest outcome for most votes. Once $\frac{1}{c}$ is estimated for a game, it is possible to tune the number of players (n) such that a satisfactory probability value p exists for a value of x. The result then determines a minimum group size for gameplay verification. For competitive games the value for x should always be greater than two to keep cheaters in the minority and ensure an honest consensus.

In practice, the exact group size may be hard to calculate because c has to be estimated. However, for any sizeable group of players (typically more than five) it is safe to assume that there are more honest players than cheaters. As a result, for any vote on game actions a majority of the votes should come to the same honest (i.e., non-cheating) outcome. In a predominantly honest group, it will therefore always be possible to identify cheaters as nonmajority votes are highly likely cheating attempts.

A voting system like this is very powerful and it is obvious that it will be valid as long as the majority of the player base is honest. It could be possible that cheaters are clustered and a group of players consists predominantly of cheaters. This may seem problematic. However, this only has limited impact because of the way cheating is generally performed. It is unlikely that cheaters collaborate in game modes with a single winner. Each cheater will attempt to manipulate the gameplay in a different way, resulting in different individual votes. In this scenario only honest players will be in agreement about game state and in the worst case no consensus is reached. A lack of consensus still signals a cheating attempt, although it may not be possible to identify which specific players were cheating. The same detection is possible for team-based game modes. If cheaters collaborate within a game of balanced teams they have a maximum of ½ of the total votes. This is insufficient for a majority of votes, again signaling a cheating attempt. In both scenarios the game session can be stopped or canceled and investigated further if needed.

This means that in practice voting is at least able to identify that cheating occurred, and in most cases it is also able to identify which players attempted to cheat.

Peer-to-Peer Protocol Design

With the basics for gameplay verification in place, the first design challenge for a peer-to-peer system is authentication. As mentioned before, a cheat-resistant system needs a strong player identity. Without a strong player identity, it is not possible to leverage the power of the combined player base – cheaters are then able to create zombie accounts and swing votes in their favor.

Nearly all game consoles and mobile and game distribution platforms already provide a basic player identity (or *profile*) information and an accompanying, secure authentication system. This platform identity and any accompanying authentication tokens can be used as the base of identity of a player in the game. In case a basic player identity is not available (or it cannot be used), an identity system has to be created. The core functionality to consider is in providing secure user authentication under *all* circumstances; multiple, well-known authentication protocols exist for such purposes, and it is unsafe to create a custom, untested protocol. It is also important that user identities are a *constrained* resource.

For an example system, we assume that user accounts are tied to game keys and that a secure login server is needed to start any multiplayer session. The login server will also provide a verifiable identity token for later use. This first peering step is called [`Authenticate`].

Now that it is possible to build a set of authenticated players, the next step is to construct a peer-to-peer mesh. The main security challenges here are integrity and efficiency. Only authenticated players should be able to connect and any new players should find other players as quickly as possible. To join a peer-to-peer network, a new player needs to know at least one other active peer node. The distribution of such initial peers should be the final step during player authentication. Either the authentication system keeps a list of active peers and selects a suitable subset for the new player or a handoff to a dedicated peer-to-peer tracker or dictionary occurs. The tracker is also responsible for verifying that peers are still connected to the network and providing updated peer selections when more connection points are needed. For security purposes, the peer selection should not be predictable, otherwise cheaters may be able to create cheating clusters in the network.

In the example system, we assume that we have a small set of trackers available. These will provide known, valid peers to any new peer with a valid authentication token. We call this step [`GetInitialPeers`].

A centralized tracker still requires datacenter resources. But unlike a client/server design it is very lightweight and can be built as a simple web service. A tracker only handles client lookups and infrequent pinging and scales to very large numbers of concurrent players without any significant investment in hardware. At the end of life of a game it can also be handed off to the fan base, keeping the most vocal and hardcore fans happy well after the game's shelf life has expired. An alternative to a centralized tracker is a peer-to-peer tracking system which keeps localized routing data on every peer in the network.

Next, message authenticity and integrity guarantees are needed. A standard solution for this is to encrypt all pairwise communication between peers. Each new peer connection should start with a security handshake that establishes any encryption keys and secrets for pairwise connections. It is safest to assume that encryption only provides confidentiality. Digital signatures and *sequence numbers* must be added to provide message integrity and protection from replay/message injection attacks. To prevent unauthorized peers from joining, the handshake also needs to verify the initial authentication token.

In the example system, we can satisfy these requirements by first using TLS/DTLS to select unique encryption and signature keys and share an initialization vector for encryption. We then use the encryption key and initialization vector for AES encryption with CBC as a block cipher mode for pairwise communication. As a final step, we verify the identity of a peer through the authentication token that was provided by the login server. If it is invalid, the connection is terminated. We call this secure connection step is [`SecurePeerConnect`].

This step has to be repeated for each peer node that joins the gameplay session. In addition, peers that drop from the network for any reason need to be replaced. (In the example system, a peer has to contact the tracker to retrieve replacement peers.)

Game History Validation Design

The next step after the previous peer-to-peer system design is to design a voting and gameplay verification system. This design depends on the game type and falls into two classes: in multiplayer games like FPS shooters, MOBAs, or strategy games, gameplay messages only propagate between a limited set of players and game state is transient. Gameplay data, except updates to the player's profile, does not persist longer than a short, single gameplay session. In contrast, MMO games have to propagate game updates amongst a very large set of players and need persistent game state.

Validating Transient Multiplayer Games

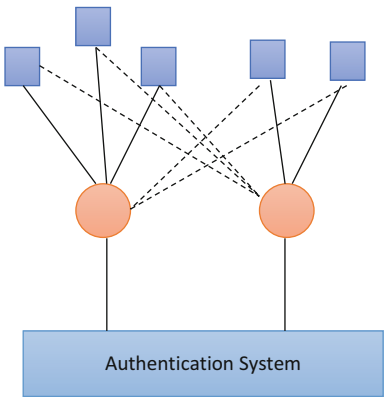
The two biggest problems in transient multiplayer games are how to find peers for gameplay verification and how to synchronize gameplay effectively.

One approach is to use lightweight game state validation through a state digest. This is only

feasible with a game engine that uses a fixed time step simulation. At a synchronized time interval in the simulation, each peer performs a one-way hash *H()* over a limited set of important game state objects *obj*, the timestamp *t,* and local player identity *id. H(obj,t,id)* is then called the local state digest. Each peer sends the local *H(obj,t,id),t,id* through a secure and reliable channel to all other peers. Other peers are then expected to validate these digests. Due to network latency, this may occur with significant delay and local copies of not yet validated *obj* for a specific *t* need to be stored. When a remote digest is received at a later time, it can be validated by creating an expected digest and comparing it to the received digest. The expected digest is created using the local game state with the remote identity: *H(obj_local, t_local,id_remote)*. If the expected digest does not match the received digest, the remote game state was altered. At this point, the peer can disconnect from gameplay and report which client was the suspected cheater. For additional safety, missing digests should also be interpreted as cheating attempts after a specific verification timeout has expired.

A more accurate cheat detection is provided by a two-tiered peer architecture design. Here, peers are divided into trusted and regular peers. A small set of trusted peers from the overall peer population serves as the arbiters and manage the other peers. We will call these trusted peers *supernodes*. These supernodes have proven over time that they are trustworthy and very unlikely to be cheaters, so their resources and trustworthiness can be used more reliably in the overall verification system. In the example system, we keep this trust information on the tracking service for additional security.

To enable gameplay validation, pick and assign at least one supernode to each existing game mode (e.g., deathmatch vs. capture the flag). It is preferable to assign multiple supernodes for redundancy and scale the number of supernodes based on popularity of a game mode. When new players join the peer-to-peer network, we now modify [`GetInitialPeers`] so they are first routed to the supernodes for their game type instead of regular peers. Supernodes then divide new peers into gameplay groups and provide the peer set to the joining peer. A gameplay group is the traditional set of players in a gameplay session. Additionally, new peers are joined to the supernode as a voting peer and may be called upon at a later point to vote on game actions. We call both join actions [`GetSecondaryPeers`]. All voting actions are handled through a dedicated connection, different from the gameplay connection. Each verifying peer is connected to at least one supernode and should never verify its own gameplay sessions. Gameplay actions are now executed and verified in the following way: when a peer performs a game action, its peers in the same session are updated directly in the same way traditional game clients would be. We call this action [`UpdateGamePlay`]. In addition, the peer sends its action and relevant game state to the supernode. The supernode forwards verification information to a set of verification peers and requests a vote. This set of peers should never be in the same game session they verify and can be across game modes (Fig. 2). Each verifying peer executes the action and returns with one vote. The supernode can then confirm or reject the gameplay action to the gameplay peer. We call this action [`VerifyGamePlay`].



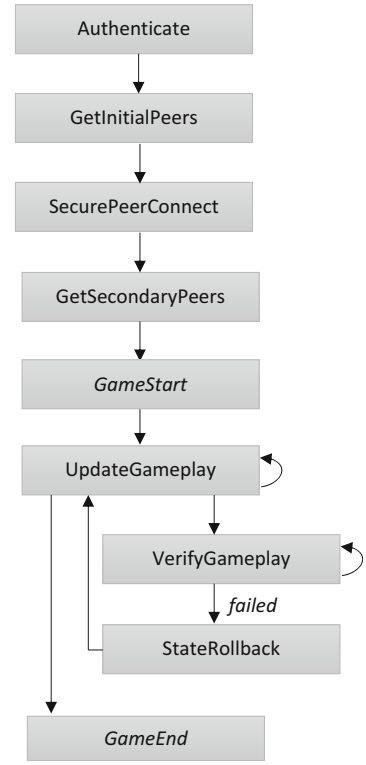
Secure Gaming: Cheat-Resistant Protocols and Game History Validation, Fig. 2 Simplified dataflow between authentication system, supernodes (*red*), and peers (*blue*). Gameplay and authentication flow is shown as a *solid line*, verification flow as a *dashed line*

Dependent on peer network resources, it may not be possible to verify all gameplay actions in all session types. A set of peers with very limited network bandwidth or incomplete connections will not be able to duplicate all game actions without impact to general game flow. Fortunately, we can often rely on the game flow for such scenarios. In nearly all games, cheating attempts are not singular events; they cause long-lasting impact on the game state. Therefore, even verifying only high-risk game actions or a set fraction of game actions can effectively reveal cheating attempts.

Verification cannot be performed as quickly as a local gameplay action. In addition to verification time, it requires at least one round-trip each between the gameplay peer/supernode and supernode/voting peer. Peers can work around this delay by opportunistically executing gameplay actions before a vote is complete. All gameplay actions are temporary accepted, but not committed until a vote confirmed. For this, the peer keeps an action history to roll back any action that is rejected at a later point. While it is not desirable to have rollbacks during a game session, they are expected to be very rare. Specifically, rollbacks should only occur during a cheating attempt. At the point of a cheating attempt, players will prefer a rollback rather than continuing with a cheated game state, even if it impacts the continuity of a game. We call this rollback action [`StateRollback`].

Once a supernode rejects a gameplay update, it can also isolate the offending peers and react appropriately. The reaction can vary from removing the cheating peers from the gameplay session and mark the cheating attempt on their profile to an immediate ban from the network.

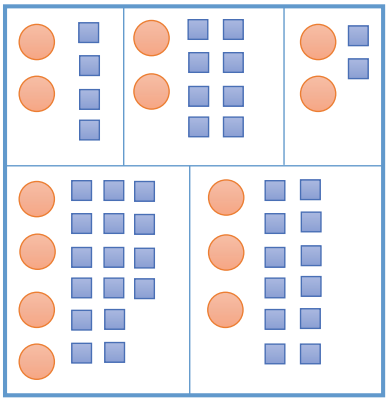
It is important that supernodes are verified on a regular basis to detect any malicious behavior. When multiple supernodes are assigned to one game mode, they can arbitrarily verify each other's behavior and the voting results that are sent to the peers. If a cheating attempt is found, the offending supernode can be reported to the authentication service. Here, it can be removed from the list of trusted peers.



Secure Gaming: Cheat-Resistant Protocols and Game History Validation, Fig. 3 Event flow for a standard peer

Validating Massively Multiplayer Games

These types of games can use the same voting design (Fig. 3), but gameplay updates need to be extended to take persistent game state storage into consideration. As a result, different segmentation of supernodes is needed. Instead of segmenting supernodes by game modes, the MMO game world is segmented into *chunks*, which represent game areas. The number of chunks will be static in most games. One supernode can handle multiple chunks, but each chunk should have at least two supernodes assigned to it for failsafe (Fig. 4). When players move into a chunk in the gameworld, they transfer to one of the associated supernodes. A chunk to supernode mapping can



Secure Gaming: Cheat-Resistant Protocols and Game History Validation, Fig. 4 Segmentation of MMO game world into chunks. Each chunk contains multiple supernodes (*red*) based on client (*blue*) population. Chunks do not need to be of equivalent size in the game world

either be provided by the tracker or negotiated amongst supernodes. This approach is similar to segmentation in peer-to-peer file sharing networks like BitTorrent and has the same constraints (Pouwelse et al. 2005).

The supernodes of a chunk and all connected peers keep its game state. Like in the previous design, game actions are executed and voted on. Similar to before, peers should not vote on actions in their own chunk to reduce the incentive for cheating. Players are less likely to cheat if it does not affect them directly.

In a system where all data is stored on peers, a high peer churn can cause issues. Therefore, it is important to ensure that game information is updated in a shared database in addition to the game state that is held on supernodes. Updates can be performed asynchronously from each supernode and merged into a time stamped game state in the shared database. This shared database could itself be a peer-to-peer system, single system, or a cloud-based solution.

Multiple copies of the same game state and a large population can significantly reduce the need for frequent backups. By requiring at least two supernodes per chunk, we can ensure basic redundancy. Further redundancy is provided by connected peers; they also keep parts of the game state. When peers leave, the supernode can provide the needed game state to new peers. When a supernode has to be replaced, the secondary supernode can be used for bootstrapping. If a conflict in states of multiple supernodes is detected, it is treated similarly to a mismatch in a game update vote.

Not relying on a shared database will work as long as sufficient supernodes and peers are present. As a result, during the early, high population lifetime of a game (Fig. 1), the shared database will only provide an auxiliary service. As time progresses and player numbers drop, the shared database will increase in importance. It becomes essential when chunks only have one supernode. It then serves to bootstrap any chunks that have lost their last supernode or are devoid of peers and supernodes.

Summary

This entry shows how to use consensus voting amongst the player population of a game to detect cheating attempts and reviews which general identity and security guarantees are needed for building a cheat-resistant game. It then focused on game protocols and outlined a design that should serve as guidance for implementing a game protocol that uses game validation to provide cheat resistance.

The presented high-level design can be implemented in multiple game types. Note that some corner cases for specific game scenarios were left out due to space constraints and may require additional design effort. The example protocol shows that it is possible to create a highly scalable, cheat-resistant peer-to-peer network that requires little to no server capacity. Once designed and implemented, such a system can be used across multiple games and handed off to players when a game is sunset. This approach significantly reduces operations costs by using player resources instead of the cloud or datacenter while providing similar cheat protection.

Semiotics of Computer Games

Mattia Thibault

Definition

The expression "semiotic of computer games" can be used both to indicate a specific semiotic-object (the system of meaning articulated and conveyed by digital games) and the discipline that studies it.

Introduction

Semiotics, literally the doctrine of signs, is a discipline focusing on meaning and interpretation. According to a famous definition by Umberto Eco, semiotics deals with *everything that can be used to lie:* if something cannot be used to lie, it cannot also be used to state the truth and, therefore, it cannot be used to say anything at all.

In the last decade, several semioticians have started to choose as a specific field of studies that of computer games. It is a field that, from a semiotic perspective, both intriguing and problematic. On the one hand, it offers interesting new ways of expressing meaning and telling stories, mixing multimedia story-telling with interaction and personalization. On the other hand, it often eludes the tools and methodologies that the discipline has polished when dealing with literature, cinema, or comics.

State of the Art

Any attempt to approach the way in which computer games organize and circulate meaning, therefore, needs a critical reassessment of its tools. For example, in his book on *cybertextuality* Espen

Aarseth criticizes harshly the practice of applying literary theory to *cybertexts* without a revaluation of its concepts (Aarseth 1997: 14). He claims that his early works on labyrinthine texts often faced misunderstanding due to the interference of literary theories. In other words, while he tried to describe the importance of texts with a labyrinthine enunciation (the cybertexts) his audience was focusing on texts with a labyrinthine interpretation (what Umberto Eco calls "open works").

Also for this reason semiotic theories of digital games are often developed in direct dialogue with game studies – more ready to recognize the novelty of the medium.

Some attempts to such a synergy have been already attempted also by game scholars. For example Mäyrä (2008: 19) borrows some terms from the semiotic metalanguage and introduces the term *ludosis*, indented as meaning making through playful action.

Due to the complexity of the discipline and of its metalanguage, however, most of the attempts of combination between semiotic theory and game studies have been attempted by trained semioticians borrowing theories and ideas and integrating them in a mono-disciplinary conceptualization.

Only a few of the "forefathers" of semiotics directly approached games as an object of study. A great number of them, however, used them extensively as a metaphor. Semioticians such as Ferdinand De Saussure, Umberto Eco, Algirdas Greimas, Louis Hjemslev, Émile Benveniste, Boris Egorov, Boris Uspensky, and Claude Levi-Strauss resorted to games in order to explain the inner workings of language, society, and even culture. Among the most commonly mentioned games, chess is the more frequently exploited, even if also playing cards have been used to this end several times. Idone Cassone (2014) summarizes several of these approaches and argues that it is the systemic structure of games that makes them particularly appropriate for such parallelism. Nevertheless, some important semioticians have indeed written fundamental pages about play – above all Juri Lotman (see Thibault 2016) and Algirdas Greimas (1980).

The first attempts to deal with *digital* games are quite recent, but a "semiotic way" to deal with video games has been outlined by several scholars all around the world (to mention few of them: Gabriele Ferri, Mauro Salvador, Agata Meneghelli, Carlos Scolari, Massimo Maietti, Matteo Bittanti, Patrick Coppock, Jack Post, Dario Compagno, Vincenzo Idone Cassone, Joaquìn Siabra-Fraile, Maria Ilia Katsaridou, Simon Levesque, Enzo D'Armenio, Gianmarco Giuliana, etc.).

Semiotic Dimensions of Computer Games

A semiotic approach to play must immediately recognize the twofold nature of this phenomenon that involves at the same time an activity (or process, or enunciation) and an objectual (or "textual") nature (see Salvador 2015). On the one hand, "to play a game" is a verb indicating an action: the engagement of a particular behavior and a specific way of interacting with objects and people. On the other hand, games involve the use and creation of several texts: digital objects and representations, but also the play sessions themselves that can be interpreted (and analyzed) as performances.

The relationship between process and text in games features many interactions. Agata Meneghelli writes that games are a *chain* of texts and practices: game design is a productive practice that creates a text (the video game) and generates a practice (to play it) that brings to light another text (the played game) (Meneghelli 2011: 25).

From this duplicity arise two of the main directions of semiotic analysis of play:

- The first one focuses on play as a *process* involving several semiotic activities: the institution of signs, a selection of saliences (i.e., which ones, of the objects of the world, are relevant or not for the activity), the acquisition of a semiotic *competence* (the knowledge of how to interpret and undertake successfully the activity), and several forms of communication – among them the metacommunication of one's playful intentions (Bateson 1955; Sutton-Smith

1997), direct communication with other players, and the spectacularization of the activity.
- The second direction of analysis focuses on the *textual* nature of play. This approach multiplies the subjects of the semiotic activity, because it encompasses also the work of game designers, i.e., the authors of the "first-level" texts. The players, therefore, would not be seen only as the authors of the *play-text*, but also as the readers of the game. This, obviously, entails a series of semiotic issues about sound narrative, visual communication, literacy and competence, and interpretation and use of the ludic texts.

There is, however, a third aspect of play that is semiotically extremely relevant: its cultural dimension. Themes such as the ludicization of culture, the social stigma that often accompanies digital games, the relationship between games and pop culture or art are also at the center of semiotic analyses.

Game-Based Learning (GBL); SG: Serious Game(s); SOG: Serious Online Game(s)

Definition

SGs are video games, which are mental competitions played with a computer in accordance with specific rules that use entertainment to enhance education, corporate training, health, public policy, and strategic communication (Connolly et al. 2012).

SOGs are online community games, which are concerned with affective learning outcomes to change not only perceptions, but also behaviors and attitudes through awareness raising on various policy issues (Fishbein and Ajzen 1975). SOGs may even aim at transforming the participants' mindset along with emotions so that they become more open-minded, humanitarian, and self-reflective primarily in their own environment, such as workplace, school, or household.

Introduction

Online games have been gaining increasing attention lately since computer technology has provided new opportunities for mobile learning. Playing online games that are embedded in social media is more than an isolated mental contest against a computer; it is both an interactive experience of a second self and a shared group action. Getting immediate feedback can induce high levels of engagement in such games, as well as a feeling of control and development. These games provide the highest degree of concentration simultaneously with social networking.

In "positive psychology," M. Csikszentmihalyi (1991) has found out that a large part of happiness is achieved by voluntary activities – half of which is determined by flow. He had found that the more often people report-reading books, the more flow experiences they claimed to have, whereas the opposite trend was found for watching television passively. Csikszentmihalyi studied people's inner states while pursuing activities that appear to contain intrinsic rewards, such as games, dance, sports, and music. He highlighted an experience of "flow state," which is the merging of action and awareness through total immersion in an activity that is challenging yet closely matched to one's skills. His work has been embraced by various fields during the Covid-19 pandemic, particularly after he passed away, since intrinsic motivation for learning and creativity has become critical for distance learning and working in isolation. By employing online formats, serious games are recognized by communities as an alternative means to promote engagement and learning. Consequently, this new venue has enhanced an optimal experience of flow along with a heightened interest in creativity, innovation, collaborative discovery, and learning, if used properly.

In this article, how "positive psychology" can contribute to the design as well as the role of positive emotions and preferences in SOG by focusing on connected and participatory gaming, that is, combining instructionist with constructionist perspectives is addressed (Isbister 2016). While the first is on having learners play conventional educational games, the latter is on having them make their own games, or co-designing together with experts, i.e., designers and psychologists.

According to the theory of flow, along with the role of positive emotions such as interest, well-being, joy, love, and empathy broaden people's momentary thought-action repertoires and

enhance learning and coping ability; as a consequence, people become more resourceful, curious, creative, and understanding (Alexiou et al. 2012). Hildmann and Hildmann (2009) have established models for GBL in classrooms. Integrating pedagogy into SOG experiences to GBL, and SOG community may fill the gaps in theory, design, and practise; such an ambitious interdisciplinary research will pave the way toward a collaborative online learning community in near future.

Overview of the Literature

The State of Flow Model

Mihaly Csikszentmihalyi (1991) outlines that the most successful websites are the ones that offer interactive experiences, not simply content. The state of flow can be created online if the following essential conditions are combined: user motivation, user telepresence, and interactivity of the web-based application. In defining "the optimal autotelic experience," he highlighted the below major factors that are applicable to digital games:

1. A challenging activity requiring skill and a dynamic balance between the two.
2. A merging of action and awareness.
3. Clear proximal goals and norms.
4. Direct, unambiguous, and immediate feedback.
5. Focused concentration on the task at hand in the present.
6. A sense of control of one's activities.
7. A loss of self-consciousness.
8. An altered sense of time, that is, loss of time awareness or time acceleration The last two components lead to full immersion and a deep state of flow.
9. Finally to: "the optimal autotelic experience" (Csikszentmihalyi 2014).

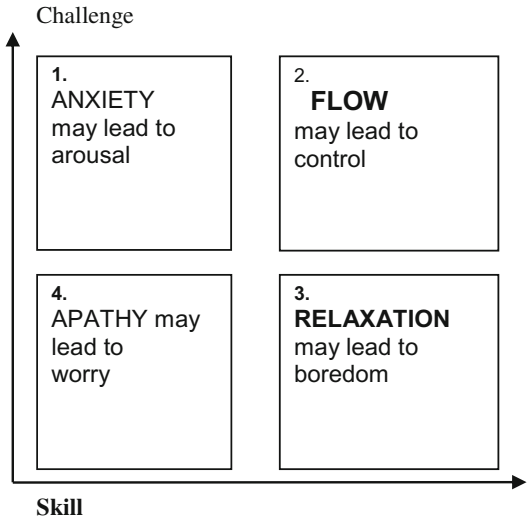
The psychological basis of this developmental process is the inducement and the use of the "state of flow." This concept is used by psychologists to describe a mental state in which the attention is highly concentrated on a specific process, the environmental information is screened out, and the person experiences a harmonious flow of its present experience (Csikszentmihalyi 1991). The state of flow is known to create a state of well-being as well as an increased perception and learning capacity.

Csikszentmihalyi initially used a simple flow questionnaire (FQ); then used the experience sampling methodology (ESM) with his flow theory to be able to analyze the balance of experiences in the following four channels with four alternative edges leading to various combinations of skill and challenge levels. ESM has been used to investigate what the participants experience in solitude through self-reporting techniques. For instance, each respondent reports their happiness levels eight times each day for a week via signals by an electronic pager. It adds up to 40 moments on a seven-point Likert scale ranging from very sad to very happy (Csikszentmihalyi 1997). That way, the flow state of happiness is operationalized and measured.

For any player to attain flow in a game or any activity, a balance needs to be achieved between the external complexity of the system or game program and the internal model a user/player develops of that particular program. A player attains a more accurate internal model of system through learning and virtual experience by trial and error (Csikszentmihalyi 1991). The four channels with respect to different levels of competence and challenges are shown on the next page with Fig. 1.

- Capability $<$ Difficulty (enter)
- Capability $=$ Difficulty (flow)
- Capability $>$ Difficulty (exit)

As can be seen from above, there are often three possible simplified scenarios of the interaction between an Internet user and an online game. When the capability of the player is lower than the level of difficulty of the game, the player will experience frustration and will abandon the game with a negative feeling. If the capability of



Serious Online Games for Engaged Learning Through Flow, Fig. 1 The inducement of the state of flow online. Motivation or pleasant frustration (discomfort) vs. boredom, if not balanced. Should I stay or should I go?

the player is higher than the level of difficulty proposed by the game, a feeling of boredom is likely to result, having as a direct effect the exit of the player from the SOG environment.

Although this quadrant model of flow is simplistic (Moneta 2012), still new empirical research venues are possible to test this general theory. Likewise, there are numerous serious academic games based on flow principles; however, FLIGBY (an online simulation game with an acronym for *FLow Is Good Business for You*) stands out as a serious game that takes all stakeholders into account, while focusing on flow experience. Moreover, FLIGBY is an ambitious gamification of flow-based leadership development simulation process that can be used both at workplace and at school.

Professor Csikszentmihalyi himself has been involved in the creation of FLIGBY to apply the three aspects of SOGs: flow/learning, technology/simulation, and fun/game. In his flow theory, Csikszentmihalyi (2003) highlights the importance of having a sufficient level of challenge and discomfort is necessary for learning and development, since one cannot grow and become humane unless confronted with ethical dilemmas to choose and draw lessons from the intended and unintended consequences of the actions.

By extending his flow theory into leadership, both learning and teaching of flow-compatible leadership values, skills, and practises through blended learning pedagogy in "flipped classroom," where lecture followed by homework and theory followed by practise are reversed, focus is on action of both individuals and groups in school. Likewise, at the workplace, benefits for individual employees lead to benefits for the whole organization. The intended purpose of this game is to help individual leaders/managers and organizations to create a flow-friendly workplace.

Originally developed as a training tool for managers, FLIGBY lets players try their hand at managing a Californian winery during 10 hours of simulation. Participants receive immediate feedback from a virtual coach named Mr. Fligby; they also get evaluative reports showing their ratings with respect to 29 leadership skills. These 29 skills as a competency system with 4 flow skills (i.e., Immediate Feedback, Balancing Skill, Timely Decision-making, and Strategic Thinking) serve as a useful tool for strategic human resource management (Marer et al. 2012).

Multiple feedbacks during (de)briefings not only strengthen an understanding and tolerance toward alternative perspectives, but also teaches empathy with others. Task- and relation-based satisfaction improves performance and commitment at work. A possible fruitful research question will be to trace the four flow-leadership skills across national cultures and determine whether they are universal or not. (Buzady 2017). Further, the quest for altruism versus non-altruism model for behavior may be tested against different cultural contexts.

Discussion and Conclusion

On the whole, systematic evaluation is an essential part of SOG, which demands an interdisciplinary perspective with a broad stakeholder

responsiveness. For this reason, research and application landscapes need to change with respect to the needs of individuals and communities simultaneously. The point of this interactive process is to make people realize their potential as individuals who contribute themselves to the overall needs of the community in the model of flow as in FLIGBY. In essence, this is the point of a communal sense of living with sharing and caring – realizing one's potential and limits as an autonomous self, and then contributing this selfhood to the community of which they are a part. The main philosophical aspect of Csikszentmihalyi's theory of flow is meaning, which is at the heart of well-being, is found through the delicate balance between the self and community; to achieve ultimate goals is not possible if one of them is totally ignored. (Csikszentmihalyi 2013). The state of flow is half of the story concerning well-being, since the personal traits along with cultural contexts have impact on happiness.

SOGs with their transformative powers may aim at raising awareness on many social issues through collaboration in the coming gamer generation. However, it has been claimed that the possibility of "cyber-activism" of alternate reality games on human suffering and the rights of distant others may pave the way to "false-activity" or "ethical-amnesia" due to compassion fatigue, rather than forging an online trustworthy community (Oliver 2010). Critical perspectives emphasize the dystopian assumptions of unconscious desires, immediate gratifications, and escapist or mindless attitudes in their reactions toward SOGs and cyberspace; therefore, the stakeholders are claimed to be at the risk of being consumed by digital games (Pelletier 2010). Other scholars have an optimist perspective since they rely on a utopian vision; therefore, they highlight the liberating potential of Internet and cyberspace. FLIGBY is based on idealist and hopeful premises of a bright future teaching trust, empathy, and understanding along with creativity and improvement of leadership.

Finally, the flow theory of Czicksentmihalyi, however, reveals the fact that it all depends on how the theoretical framework is linked to the practise through the multifaceted nature of SOGs. How SOGs are designed, implemented, and analyzed have to be considered thoroughly with user tests before their final evaluation. Well-defined and well-designed SOGs can offer an antidote to our concerns about the de-sensitizing effect of information overflow, interweaving of work, technology, home life, and leisure. In SOGs, making difficult choices and coping with their consequences at different levels of analyses, active and optimal learning might be enhanced.

Ordinary life with its issues and incompatible trade-offs is progressively becoming the imaginary world of SGs and SOGs; for instance, *Fligby, Second Life,* and *SimCity*. Through the convergence of several technologies and social forces accelerated by Covid-19, Metaverse is the latest simulated extension of the real world. One can still hope for and imagine a future SOG community, whereby nurturing and loving experiences even in intimidating landscapes with crises may bring people together, rather than apart. Although scientific and artistic curiosity will continue to be a potential usage of SOGs that go beyond the representation of reality, they are most convenient at schools and workplaces for learning real and mundane issues.

While Csikszentmihalyi's ideas come from a psychological foundation, they aid serious game designers and evaluators to realize the significance of an emotional connection when creating a new game as a product. Researchers will increasingly concentrate on how to create games that make people happy at work, school, and home since positive emotions and attitudes enable and enhance productivity and success. His theory of flow and ESM method gives the information and game community food for thought with numerous significant theoretical and practical implications.

In sum, the SOG designers need to be aware of how relevant stakeholders connect and relate themselves within a particular conceptual model. The flow concept is being adopted to different

contexts and contents; therefore, systematic reviews, meta-analysis studies, and evaluations are important for new SOGs. Further, co-designing with experts is suggested here so that the primary connection between flow, design, and evaluation cycle may be continually, if not continuously reread with the feedbacks of all stakeholders. Community and individual norms and standards are relative to each other and connected with each other in the flow model. SOGs in future may only be improved in terms of how they are designed as a process (gamification), by whom and for whom they are designed (stakeholders), and for what purpose they are defined and evaluated (goal and norm). (Csikszentmihalyi 2003).

The opportunity to use the power of SOG to assist psychological interventions will continue; however, its role to enhance education and management/leadership is conceivable in near future. The challenge is the difficulty of unlearning, relearning (resetting), and learning in a different format due to "the creative destruction of new technologies" like the Metaverse ecosystem. "The perennial gale of creative destruction" is an essential fact of capitalism according to Schumpeter (1942), since new production/service units and processes replace outdated ones for optimization. The seeds of this new ecosystem are being planted; whether one or many metaverse platforms will unfold is yet to be seen.

Shadow Shooter: All-Around Game with e-Yumi 3D

Masasuke Yasumoto
Department of Information Media, Kanagawa Institute of Technology, Kanagawa, Japan

Definition

I introduce here "Shadow Shooter," AR shooter game. It uses a bow interface system called "e-Yumi 3D" and real physical interactive content that changes a 360° all-around view in a room into a virtual game space.

Introduction

In this entry, I will introduce Shadow Shooter and e-Yumi 3D. The development of computer games and devices associated with them (e.g., Kinect and Wii) has continued to advance, which has enabled players to combine their physical capabilities and motions with games and sports in a virtual world. Additionally, various studies have been done that focus on playing virtual games or sports using a particular device. However, such devices and games can only use gestures or basic motions of games and sports, and it is difficult for players to achieve a strong sense of reality.

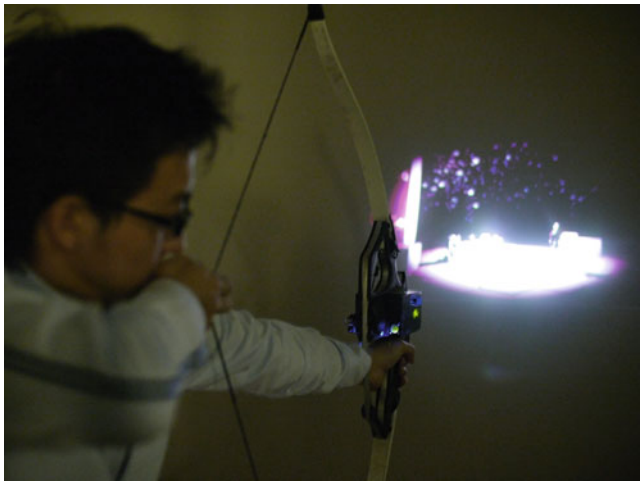
Some studies have used components of real sports equipment as devices in order to improve the user experience (Geiger et al. 2013; Owetschkin et al. 2013; Yasumoto 2013). Geiger's Virtual Archery (Geiger et al. 2013) and Owetschkin's Mobile Virtual Archery (Owetschkin et al. 2013) use a real bow as an interactive device to create positive user experiences. However, they respectively require a large projection screen and a smartphone screen as a display, so users are likely to fail to recognize real-scale distances between themselves and the shooting targets in a virtual world. The Light Shooter (Yasumoto 2013), my previous interactive content, also uses a real bow device – the Electric Bow Interface (Yasumoto and Ohta 2013). This device recognizes all directions that arrows are shot in and projects real-scale targets, which are animals and humans with biological motion. However, it displays directions only with a standing projector; thus, users cannot get a strong sense of reality all around them.

Against this background, I constructed Shadow Shooter that uses the e-Yumi 3D interface and real physical interactive content that changes a 360° all-around view in a room into a virtual game space (Fig. 1). This system was constructed by developing my previous interactive Light Shooter content. Shadow Shooter expands the virtual game space to all the walls in a room just as in Jones' RoomAlive (Jones et al. 2014); however, it does not require large-scale equipment such as multiple projectors. It only requires the e-Yumi 3D device, which consists of real bow components added to Willis's interface with a mobile projector (Willis et al. 2013). In this paper, I describe the construction of e-Yumi 3D and the concept of Shadow Shooter.

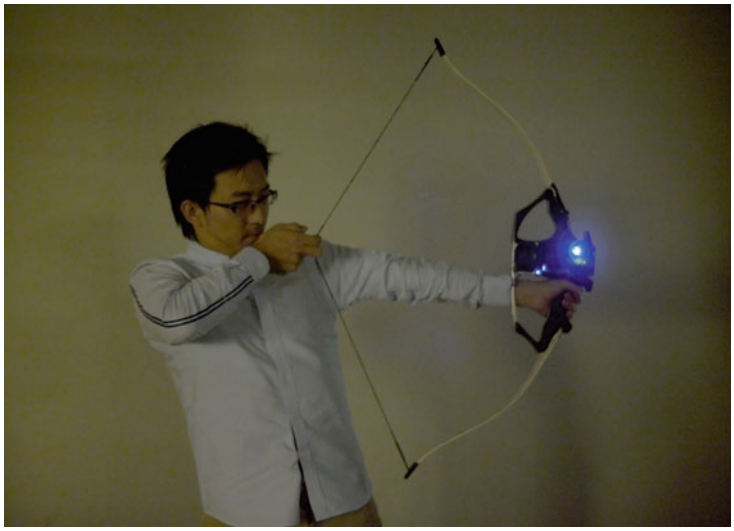
State of the Art Work

e-Yumi 3D Hardware

I introduce my e-Yumi 3D system. As shown in Fig. 2, e-Yumi 3D is based on an real archery bow and also includes a mobile laser projector, a 9-axis sensor (3-axis accelerometer, 3-axis digital compass, 3-axis jyro sensor), two strain gauges, Arduino Nano and its control board, a Windows PC, a speaker, and a battery. The 9-axis sensor is connected to the PC via a USB and is used to detect the direction of bow. The degree that e-Yumi 3D's string is drawn is correctly calculated from parameters of the strain gauge with Arduino Nano and its control board. Additionally, the shooting of the e-Yumi 3D can be detected from the strain gauges on the bow's upper limb.



Shadow Shooter: All-Around Game with e-Yumi 3D, Fig. 1 Depiction of Shadow Shooter in use



Shadow Shooter: All-Around Game with e-Yumi 3D, Fig. 2 e-Yumi 3D

Therefore, the arrow is virtual, but its track seems to be real.

Game Engines

I use Unity for this Shadow Shooter as a game engine and the sensor server software. I use two kinds of sensors, 9-axis sensor and strain gauge. Strain gauge connects Arduino Nano and Unity connects Arduino Nano via USB. However, 9-axis sensor connects a Windows PC directly. Because Unity cannot recognize the DLL for 9-axis sensor, this sensor server software connects 9-axis sensor and gets information once. Next, the sensor server software connects Unity via Win Socks and send information.

Graphics Expression

In this game, players cannot watch the figure of enemies. In the screen, there are a lot of dots. Some dots are moving randomly, and some dots are moving biologically. I use biological motion for enemies' animation like The Light Shooter. Additionally, there are shadows. Players cannot watch the enemy directly, but if player shoots the

arrows, they illuminate the shadow of enemies, so players can recognize them as shown in Fig. 3.

I recommend players play Shadow Shooter in the dark room. Players cannot see anything but if players aim the walls, ceiling, or floor of the room with the e-Yumi 3D, images of game are shown with a flashlight in hand in the darkness. This Shadow Shooter is like horror shooting game.

Overview

Shadow Shooter needs the e-Yumi 3D and dark room. In the room, players equip e-Yumi 3D and aim anywhere, e-Yumi 3D detects the direction of the bow with 9-axis sensors in it, and projects the image of the same direction of the virtual world of Shadow Shooter with a mobile laser projector in it. Players can play the 360° horror shooting game as an immersive game like using HMD, but this system does not need HMD.

Experiments and Show Cases

I exhibited this Shadow Shooter as playable in several countries in the world , CEDEC 2014, Laval Virtual Revolution 2015 (Fig. 4), and Tokyo Game Show 2015.

Definition

Shape deformation models have occupied a prominent place in computer graphics and image processing. They possess superior geometric properties of flexible nature which make them an ideal candidate for several applications in graphics and imaging industry. In this article, some basic properties of shape deformation models are presented. These properties are highlighted though examples. An industry application with respect to topology driven structures through deformation with 3D shape correspondence of varying nature further highlights the strength of these models.

Introduction

The deformation of shapes corresponds as a basic problem in geometric modeling (González Hidalgo et al. 2013). Several methods have been developed to address rigid alignments, isometric shape articulations, part stretching nonrigid shape deformations, etc. Considering the inherent matching shapes dissimilarity, the search for correspondence becomes complex with respect to formulation of the problem computation cost. In

order to deal with shapes varying in structure as well as geometry, the current techniques are basically data or knowledge based. They make use of various supervised learning or unsupervised co-analysis for collections of shape. In terms of design, these techniques give coarse as well as discrete correspondences which leaves structural discrepancies considering matched parts or their ensembles unsettled. Some examples worth mentioning are available in (Chaudhuri 2018).

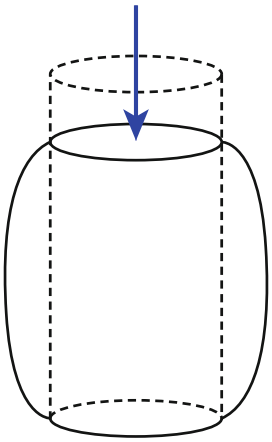
The deformation process can be represented through hierarchy modeling which effectively represents object geometrically. Though this simple graphical primitives along with operators are combined together towards the formation of complicated objects. In the hierarchy of leaf nodes, there are hardware commands from where vectors are drawn, individual pixels' colors change, and operations are performed on list of segmented polygons. With respect to proper algorithms, the users have strong intuitive feeling for manipulation of results. They can also think for every operation and can structure the objects they are looking for. These deformations enforce the user to consider an object from special topology that can be bent, twisted, tapered, compressed, expanded, or transformed towards a final construct. They have highly intuitive nature. They have visualized operations which simulate some kind of manufacturing processes towards objects' fabrication. These deformations have also been considered towards traditional CAD/CAM modeling as well as surface patches. This decreases the data storage requirements, which simulate flexible objects geometrically. This makes it possible towards accurate modeling of physical properties for various elastic materials considering several partial differential equations. However, simple mathematical deformation techniques also exist. These simple techniques have reduced requirements in terms of computation. They model objects effectively.

A fair amount of work has been done on matching discrete structures, deformation driven correspondence, structure aware deformation, topology matching and blending, as well as co-analysis. This is in lines with deformations of shapes where the 3D geometrical structures are actively used. With this motivation, in this article we present some basic concepts related to shape deformation which are supported with illustrative examples. An industry application revolving around a deformation driven technique considering varying topology with shape correspondence in 3D is highlighted. This article is structured as follows. In proceeding section, the shape deformations overview is given. This is followed by an industry application in shape deformations. Finally, the conclusions are given.

Shape Deformations: Overview

The shape deformation can be defined as any object's shape change which happens because of a force applied externally or temperature change. For shape change of an object, the deformation energy is transferred through work done. For temperature change, the deformation energy is transferred through heat. The first instance is attributed towards tensile and compressive forces as well as shear, bending, or torsion. The second instance is determined through temperature and is the structural defects mobility where the movement is thermally activated. The deformation also results from strain. The deformation is also associated with stability of an elastic material through incremental deformations. It is based on superposed small deformation considering an equilibrium solution. When deformation takes place, the internal forces of inter-molecular nature take place that opposes the external forces. If external force is not adequate, the forces are enough towards fully resisting said force. This also allows objects towards new equilibrium and return to actual state as the load withdraws. The greater external forces will go towards object's full deformation as well as its structural distortion.

Figure 1 shows that compressive loading which is shown by arrow causes cylinder deformation such that original shape shown by broken lines is deformed considering sides which are bulging. The sides bulge as material because it is



Shape Deformation Models, Fig. 1 The object deforms because of stress (it shortens, and expansion takes place in outward direction)

not strong enough to break or support any load. This results in forcing the material out laterally. The internal forces at right angles to deformation resists applied load. For negligible deformations, the object may be considered as rigid body.

We now present the basic mathematical formulations for shape deformations which are specified through global and local deformations. The global 3D solid deformation is mathematical function $\overline{H}$ that changes global coordinates towards points specified in space. The points for undeformed and deformed solids have been specified through $\overline{a}$ and $\overline{A}$, respectively. This is represented as:

$$\overline{A} = \overline{H}(\overline{a}) \tag{1}$$

Let us consider a_1, a_2, and a_3 as the components of 3D vector $\overline{a}$ in three directions.

The local deformation changes tangent space for solid. The differential vectors for solid's substance are circulated and skewed accordingly. There is an integration of these vectors considering the position globally.

There are separate chain links considering differential vectors that may stretch as well as rotate. The deformation's local specification is given by matrix function which may be circulating as well as skewing. The end link's position considering chain is vector sum for previous links and is discussed here.

Considering the modeling aspect, the two important vectors are tangent as well as normal. The first vector is used towards delineation and construction of local geometry. The latter is used towards orientation of surface as well as information for lighting. There is a transformation for the tangent as well as normal vectors from the undeformed to the deformed surface. The manipulations towards rules of transformation consider single multiplication with respect to jacobian matrix $\overline{\overline{JM}}$ for transformation function $\overline{H}$. The jacobian matrix $\overline{\overline{JM}}$ considering transformation function for Eq. (1) is function of $\overline{a}$ and is computed through partial derivatives for $\overline{H}$ with a_i; $i = 1, 2, 3$ such that:

$$\overline{\overline{JM}}_i(\overline{a}) = \frac{\partial \overline{H}(\overline{a})}{\partial a_i} \tag{2}$$

As such, ith column for $\overline{\overline{JM}}$ is achieved through partial derivative for $\overline{H}(\overline{a})$ considering a_i. The object's surface is represented through parametric function for variables p and q such that:

$$\overline{a} = \overline{a}(p, q) \tag{3}$$

Any tangent vector considering the surface is reached through linear combinations of partial derivatives for $\overline{a}$ considering p and q. The normal vector direction can be obtained through cross product for linearly independent tangent vectors considering surface.

The transformation rule for tangent vector is restated in terms of a chain rule. As a result of this, new vector derivative is jacobian matrix times the previous derivative such that:

$$\frac{\partial \overline{A}}{\partial p} = \overline{\overline{JM}} \frac{\partial \overline{a}}{\partial p} \tag{4}$$

In component form, the above equation can be written as:

$$A_{i,p} = \sum_{j=1}^{3} JM_{ij} a_{j,p} \tag{5}$$

The transformation rule for normal vector requires jacobian matrix inverse transpose such that:

$$\overline{\boldsymbol{n}}^{(A)} = \det JM\overline{\overline{JM}}^{-1T}\overline{\boldsymbol{n}}^{(x)} \quad (6)$$

Since only normal vector's direction is significant, it is not required to calculate determinant's value. The jacobian's determinant looks towards local volume ratio for each transformation point considering deformed as well as undeformed regions. Scaling is one of the simple examples of shape deformation (https://abaqus-docs.mit.edu/2017/English/SIMACAECAERefMap/simacae-t-customdeffactorframe.htm). Other notable examples include global tapering along any axis, global axial twists, global linear bends along any axis (https://abaqus-docs.mit.edu/2017/English/SIMACAEGSARefMap/simagsa-t-displayingandcustomizingadeformedshapeplot.htm), etc. We present few of these examples here.

Global Tapering Along Any Axis

The tapering operation is identical to scaling. It has been applied towards many flexible objects. It is achieved by differentially changing two global components' length without changing third component's length. The process is represented through piecewise linear function which decreases as the other axis increases. Figure 2 represents tapering of any ribbon.

Global Axial Twists

The global axial twists basically simulate an object's global twist. The twist is approximated through rotation achieved differentially. It draws analogy from the global basis vectors' differential scaling. Here rotation is performed in terms of global basis vectors' pair which is height's function where third global basis vector is not altered. This deformation process is enforced through twisting a cards' deck with every card being rotated somewhat more than the card below it. Figures 3, 4, 5, and 6 represent global axial twists process for several objects of interest such as ribbon's progressive twist, two primitives' progressive twist, tapered primitive twist, and twisted offset primitive tapering.

Global Linear Bends Along Any Axis

The global linear bends along any axis mimics the bending simulation process. It is basically represented through bend of isotropic nature considering centerline parallel with respect to any specified axis. During bending process, centerline stretch does not change. The angle at bending is always constant considering extremities. However, all the changes take place linearly considering central part. Considering region at bent, rate of bending is kept fixed, and differential basis vectors are rotated and translated with respect to the third local basis vector. The deformation comprises of rigid body rotation as well as translation outside bent region. Here range of bending deformation is controlled through specified axis. Figures 7, 8, 9, 10, 11, and 12 represent global linear bends along any axis for several objects of interest such as region's progressive bending, region's progressive change in bending range, moebius band produced through twist and bend, tapered primitive with bents and twists, bent and

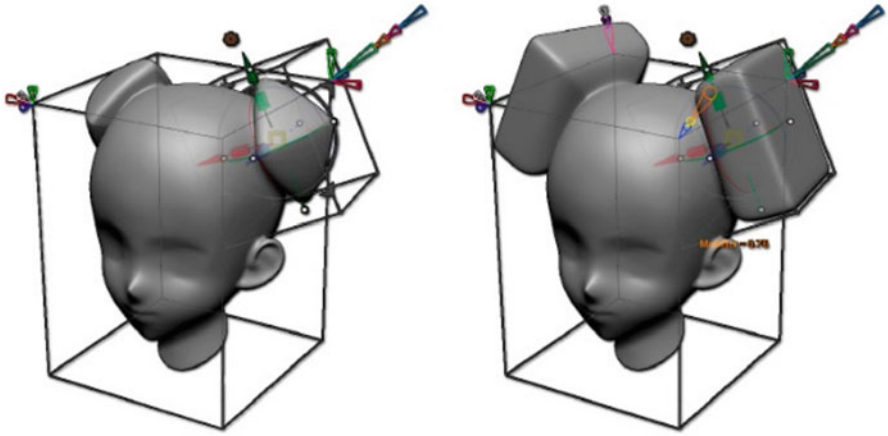
Shape Deformation Models, Fig. 3 A ribbon's progressive twist



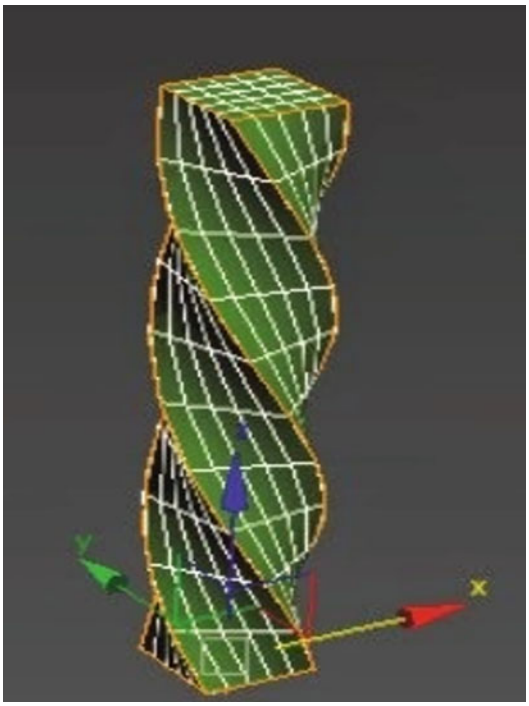
Shape Deformation Models, Fig. 4 The two primitives' progressive twist

Shape Deformation Models, Fig. 5 The tapered primitive twist

twisted primitive and chair's model considering six primitives with seven bends.

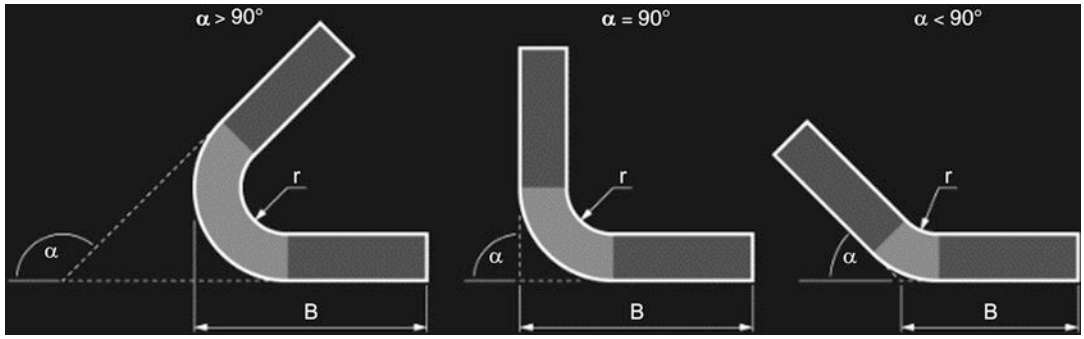
Now we discuss the process for generating more generalized shapes. In this direction, it converts local representations towards global representations with respect to shape deformations. The Jacobian matrix is generally known beforehand as a function of its parameters. However, the expression with closed form considering deformation function is not specified. The basic method revolves around the following steps:

(a) The undeformed input shape's conversion into its tangent vectors considering differentiation
(b) The tangent vectors' transformation through tangent transformation considering tangent vectors with respect to object deformed
(c) The integration of new tangent vectors towards new position vectors for deformed curve, surface, or solid spaces

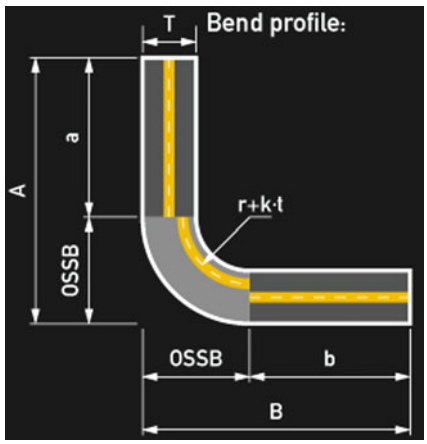


Shape Deformation Models, Fig. 6 The twisted offset primitive tapering

The local towards global operations changes local tangent vectors and Jacobian matrix in terms of position vectors globally. The space's absolute position for deformed object is specified within arbitrary constant vector integration. This gives complete deformation description which can



Shape Deformation Models, Fig. 7 A region's progressive bending



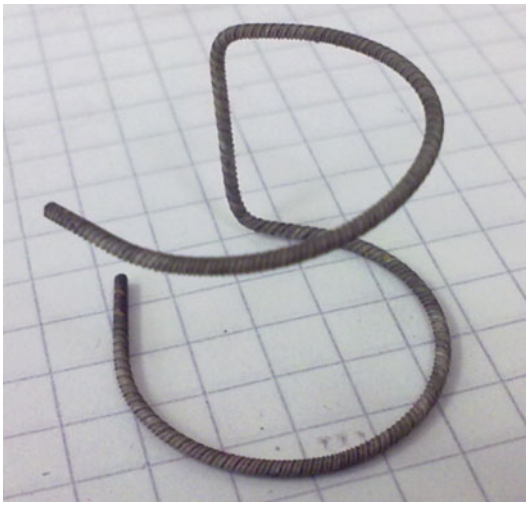
Shape Deformation Models, Fig. 8 The bending range's progressive change for a region

Shape Deformation Models, Fig. 9 The mobius band that is developed through bends and twists

be directly coupled towards output considering elasticity equations or finite element analysis for entities of deformable nature describing general shapes' composition. To further augment this discussion, two significant applications include space curves as well as 3D surfaces and solids transformations available in (Chaudhuri 2018).

Another application of shape deformation worth mentioning is available in rendering (Chaudhuri 2018). To achieve the control points and normal vectors set for which the surface patches with polygons or splines are developed, the surface deformed is sampled parametrically. Considering proper sampling, patches can deform the target object in more detailed manner when surface curvature is high and lesser detail where there is flatter surface. With the parametric values for raw grid, the object is at first sampled. The raw parametric surface's sampling is refined through vector criteria normally which is compute considering rule of transformation. There is recursive subdivision for adjacent normal vectors where divergence is large. The dot products that are wide enough from unity indicate that large recursive detail is required for that part. Therefore, patch-based methods such as depth buffer as well as scan line encoding schemes are good. There is linearity in these algorithms with respect to total surface area as well as number of patches. The direct subdivision approach is not suitable towards ray tracing as the total number of operations becomes quadratic considering number of ray comparisons and objects. In order to reduce the number of objects, the incident ray is intersected with deformed primitives analytically. The inverse deformations can also be used

Shape Deformation Models, Fig. 10 The tapered primitive with bents and twists



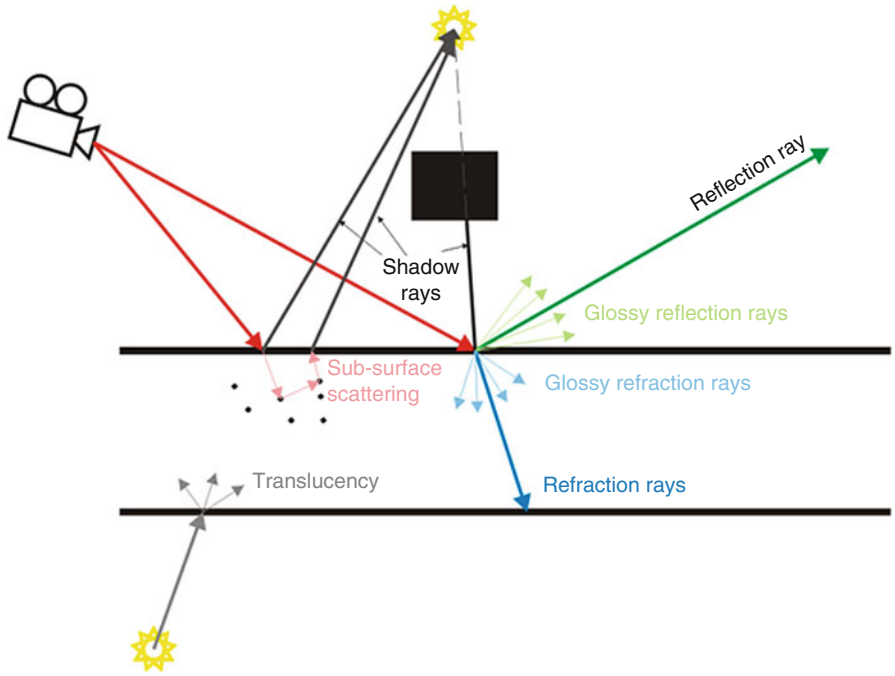
Shape Deformation Models, Fig. 11 A bent and twisted primitive

to undeform primitives as well as tracing along deformed rays. Figures 13 and 14 represent the primitive of deformed nature in undeformed space and undeformed primitive with respect to undeformed coordinate system considering ray's path. This reduces dimensionality for parameter search considering three towards one which indicates considerable benefits in terms of computational complexity.

Shape Deformation Models, Fig. 12 The model of chair considering six primitives with seven bends

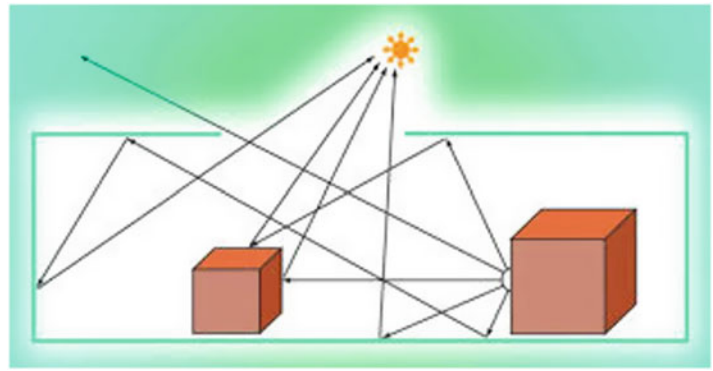
Industry Application

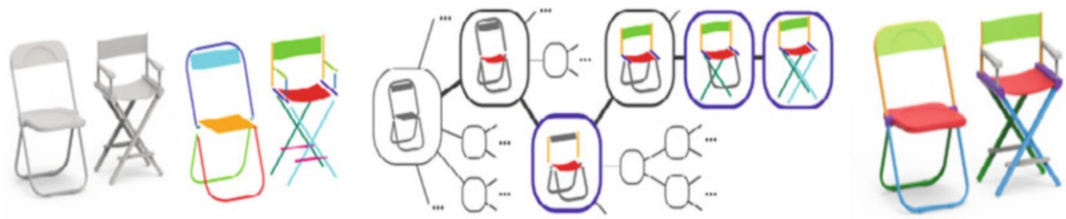
In this section, a novel industry application revolving around a topology driven through deformation with 3D shape correspondence of varying nature. The 3D geometry enforces shape deformation algorithm to consider 3D shapes as inputs (Alhashim et al. 2015). This allows more generalization for the deformation models. The input shapes are upright oriented and segmented as significant parts adhering to all the symmetries. The shapes are represented through shape's topology encoding considering parts' medial abstractions and structural relations with respect to various connectives and symmetries. A combinatorial tree may be traversed to reach part correspondence with pruning of priority nature. The priority is enforced through self-distortion energy. The evaluation is performed considering deformation from one shape to another under previously matched parts' constraints. This produces piecewise continuous part-to-part mapping. Figure 15 highlights a typical correspondence approach (Alhashim



Shape Deformation Models, Fig. 13 The primitive of deformed nature in undeformed space

Shape Deformation Models, Fig. 14 The undeformed primitive with respect to undeformed coordinate system considering the ray's path





Shape Deformation Models, Fig. 15 A typical correspondence approach (with target shapes and curve-sheet abstractions on extreme left, the search tree in middle part, and final correspondence result on extreme right)

et al. 2015). For shapes having large number of parts, course towards fine approach is adopted when search is performed for optimum correspondence. The correspondence may be from all the source parts to some target parts, but the reverse is not valid. Therefore, several source parts can be matched towards identical target part. However, there might be unmatching for certain target parts. The deformation energy determines which source to target designation yields the best solution.

This deformation model considers geometric as well as topological operations like part split, duplication, merging, etc. which leads towards fine-grained and piecewise results. The key aspect here is the deformation energy which affects geometric distortion. It also encourages preservation of structures as well as allows changes in topology. It accomplishes this by connecting shape parts through structural rods that behave in a similar manner as virtual springs. It allows encoding for energies coming from geometric, structural, and topological shapes. The optimal shape correspondence is reached considering the pruned beam search.

This process can be sketched as consisting of four steps, viz., initial segmentation, graphical structured representation, self-distortion energy, and correspondence search. The initial segmentation looks towards computation of fine-grained correspondence parts. The graphical structured representation defines the shape of segments as significant concrete structures achieved through various methods. The self-distortion energy is measured considering shape of the source which allows several shape distortions. The correspondence search allows one-to-one as well as one-to-many part correspondences. Figure 16 shows an array of fine-grained part correspondences calculated using this method.

Conclusion

In this article, we have presented some of the important conceptual aspects related to shape deformation models. The shape deformations find immense applications in computer graphics and image processing. Some of the basic properties of shape deformations are initially highlighted followed by illustrative examples. An industry application considering topology driven structures through deformation with 3D shape correspondence of varying nature justifies the significance of the shape deformation models.

Shape Deformation Models, Fig. 16 The array of fine-grained part correspondences calculated using this method (Considering each pair of input 3D models, the best-rated correspondence is shown; The matching parts have identical color and others non-matching parts are in gray)

Definition

The MANET network is a network of wireless hosts that can be mobile. In MANET networks, the mobility of the nodes may change the path between the two nodes and this makes them different from other wireless networks.

Introduction

Wireless networks consisting of several nodes have no centralized infrastructure. Routing causes data to be transmitted from source to destination. An effective way to estimate the performance of these networks is to simulate the performance of different protocols depending on the environment and the type of simulator used. In this article, the performance of both AODV and DSDV protocols in terms of metrics was evaluated. Cellular systems will no longer sustain the recent, rapidly growing demand for applications like VoIP, Internet surfing, online games, etc., due to their limited capacity and data rate.

Ashheb study reveals that two protocols AODV and DSDV have been simulated using NS-2 simulator and compared in terms of packet delivery fraction, end to end delay, and throughput in different environment, varying period of pause time and the number of expired nodes. Simulation results show that AODV routing protocol has better performance in terms of packet delivery fraction and throughput but AODV suffers from delay (El Ashheb 2012). Neetu et al. discussed the performance of DSDV and AODV routing protocols measured using the different performance metrics such as Packet Delivery Fraction, Average End to End delay, and Routing Overhead under two different scenarios, with changing pause time and changing number of nodes. It was observed that the performance of AODV routing protocols is much superior as compare to the DSDV routing protocol (Neetu 2012).

MANET Networks

The MANET network is a network of wireless hosts that can be mobile. No prefabricated infrastructure is used in these networks (necessarily). That means, there is no infrastructure such as a central station, router, switch, or anything else that is used in other networks to help with network structure. Rather, there are only a few wireless nodes that connect to non-neighboring nodes by connecting to neighboring nodes (Suman et al. 2009).

In MANET networks, the mobility of the nodes may change the path between the two nodes and this makes them different from other wireless networks. Despite all these problems, MANET networks are used in many cases. The reason is the speed and ease of implementation of this network, as well as its reliance on pre-built structures.

Uses of MANET networks include personal applications such as connecting laptops to one another, general applications such as communication between vehicles and taxis, military applications such as military and fleet communication, and emergency applications such as rescue operations. Now days we have latest several multimedia applications such as digital television, video conferencing, web games, and real-time interactive audio and video streaming which needs high throughput and less amount of end to end delay which are main essential quality of service metrics (Sharma and Trivedi 2016).

AODV and DSDV Protocol Performance

Using Flooding Algorithm for Data Transfer

The simplest solution to the problem of routing in wireless networks is to transfer information through flooding. This is the way the sender sends information to all of its neighbor nodes. Any node that receives a packet sends this information to its neighbors. To prevent a node from sending a packet more than once, a sequence number is used for each packet. Each receiver thus controls the sequence number of the packet and sends it to its neighbors if it is not a duplicate. This method will definitely reach the destination, but once the destination has been reached, the flooding operation will continue to reach all the nodes in the packet (Kumar and Miglani 2009).

As is clear, the main advantage of this method is first of all its ease of implementation and secondly the assurance of destination-based access. However, one major drawback to the scheme is that data packets are often high in volume and, as explained in this way, data may travel the distance without needing to. For example, suppose a node decides to use data to send to its neighbor node. Now if you want to use the flooding method, this packet will be distributed all over the network. If you know the neighborhoods of the nodes, you can greatly reduce this information transfer.

This drastic increase in network load does not allow the flooding method to transfer information. But this method is widely used in moving control signals due to the small volume of these signals. Control packets are packets that are used to obtain the route and are the routes used to send the data (Vijayalaskhmi et al. 2011).

DSDV Protocol

The Destination Sequenced Distance Vector protocol (DSDV) is based on the classic Bellman-Ford algorithm. In this case, each node provides a list of all destinations and the number of jumps to each destination. Each list entry is numbered with a number. Incremental packets are used to reduce the amount of traffic caused by network updates. The only advantage of this protocol is to avoid the creation of routing loops in networks containing mobile routers. This way, route information is always provided, regardless of whether the node currently needs to use the route. The disadvantages of the DSDV protocol require parameters such as the timeframe for updating information and the number of updates required (He 2002).

AODV Protocol

In the Advanced On-demand Distance Vector algorithm, unlike the previous algorithm, it does not place the path in the packet header. So, each node controls the table it already has when receiving RREQ. If the path of final node exists on your table, then the RREP issued. Otherwise, it broadcasts the RREQ message. Certainly RREPs can be sent back to the RREQ transmitter node. In order for a middle node to know if the path he knows is newer to the request, a sequence number is used in the RREQ messages. Thus, only if the RREQ sequence number is less than the path sequence number, the RREP message is issued by the middle node (Bobade and Mhala 2012).

Other Algorithms

There are many other algorithms for routing in wireless networks. These algorithms include location-based algorithms such as LAR and DREAM. These algorithms predict the current position of a node using information such as the previous position and speed of a node and send the message only to the same region. Due to the multitude of routing algorithms in these networks, just a few specific algorithms in this article were mentioned.

NS-2 Simulator

NS-2 is a computer network simulator based on discrete and object-oriented simulator. Written by C++ and Otcl programming languages, it is one of the most useful tools for simulating local and wide area computer networks.

Simulation and Comparison of AODV and DSDV Protocols

The simulation is performed on 50 randomly moving nodes in an insecure wireless network that has 25 source nodes with TCP application and CBR traffic type, maximum packet size is 1000 bytes and 25 destination nodes is selected using LossMonitor and TCP pattern.

In this discussion, each node with a node number sends information to a node with an odd number of units at a time, the nodes moving randomly in a wireless environment. The scenario presented by the two types of AODV and DSDV protocols is applied to the nodes in the environment.

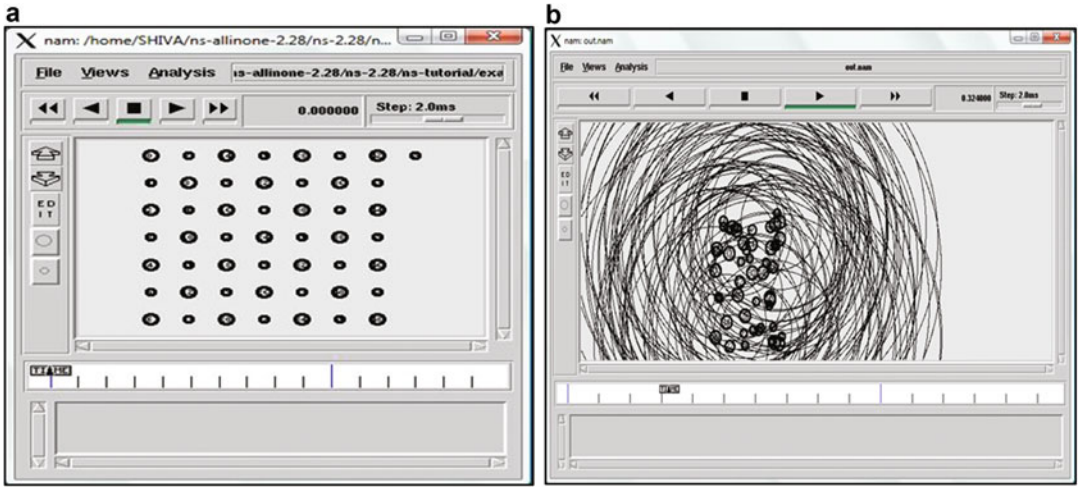
Nam is a Tcl/TK-based animation tool for viewing network simulation traces and real world packet traces. It supports topology layout,

packet level animation, and various data inspection tools. Nam with 50 nodes is shown in Fig. 1a. Figure 1b shows NAM with transmission information.

Scenario1: AODV Protocol with 50 Nodes

The parameter specifications of the scenario1 with the AODV protocol are presented in Table 1. Parametric specifications are number of nodes, simulation time, type of traffic, etc.

At the beginning of the scenario1, both the bandwidth metrics and the number of packets loss are zero. Packets loss occurs when one or more packets traveling across a network fail to reach their destination. Packet loss can be caused by a number of factors, including signal degradation over the network, oversaturated and highly congested network links, corrupted and faulty packets rejected, and faulty networking hardware (Rathee and Verma 2009). After the CBR is applied to the nodes, the movement of nodes around the number of packets loss per unit of time is increasing and is graphically displayed. The performance of AODV protocol is shown in Fig. 2. The green chart shows the number of packets received and the red chart shows the packets loss. As you can see, as the number of packets received increases, as well as the number of packets loss increases.

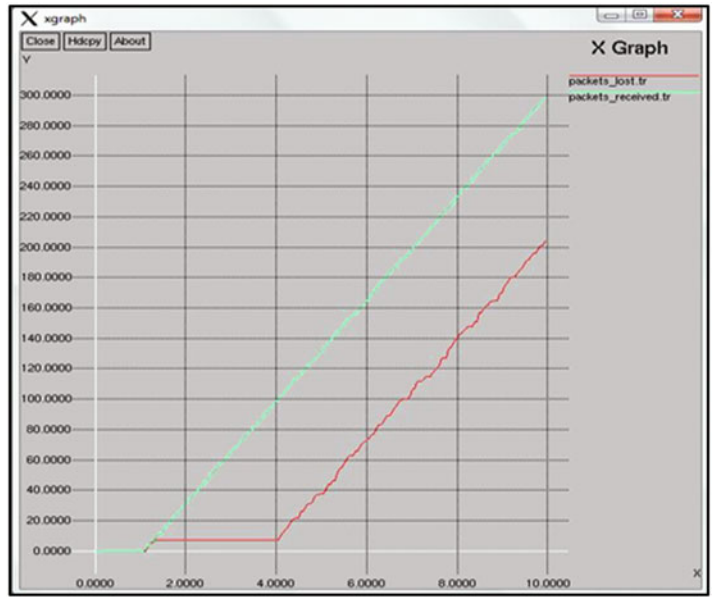


Simulation and Comparison of AODV and DSDV Protocols in MANETs, Fig. 1 (**a**) NAM with 50 nodes. (**b**) NAM with transmission information

S

Simulation and Comparison of AODV and DSDV Protocols in MANETs, Table 1 Parametric specifications of scenario1

Parameter	Value
The number of nodes	50
Simulation time	10 s
Type of protocol	AODV
Environment size	800 × 400
Type of traffic	CBR
Packet size	1000 byte
Simulator version	Ns-2.28
Antenna type	Omni antenna



Simulation and Comparison of AODV and DSDV Protocols in MANETs, Fig. 2 The performance of AODV protocol

Simulation and Comparison of AODV and DSDV Protocols in MANETs, Table 2 Parametric specifications of scenario2

Parameter	Value
The number of nodes	50
Simulation time	10 s
Type of protocol	DSDV
Environment size	800 × 400
Type of traffic	CBR
Packet size	1000 byte
Simulator version	Ns-2.28
Antenna type	Omni antenna

Scenario2: DSDV Protocol with 50 Nodes

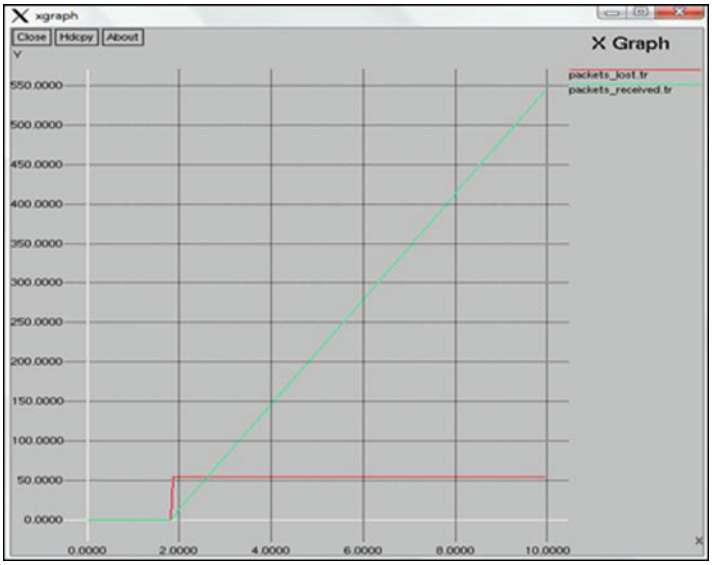
The Parameter specifications of the scenario2 with DSDV protocol are presented in Table 2. At the beginning of the scenario2, both the bandwidth metrics and the number of packets loss are zero. So, the only difference between scenario1 and scenario2 is in the type of protocol. The performance of DSDV protocol is shown in Fig. 3.

Performance Comparison

The number of packets loss in AODV increases with increasing simulation time, but this criterion in DSDV decreases with increasing simulation time and follows a constant rate. Therefore, in wireless networks, if there is less time to transmit data, it is better to use the AODV protocol because it has fewer packets loss.

Conclusion

In this article, the performance of both AODV and DSDV protocols in terms of metrics was evaluated. NS-2 simulator for comparison the performance of AODV and DSDV protocols is used. Both AODV and DSDV protocols can be used in environments where there is more communication



Simulation and Comparison of AODV and DSDV Protocols in MANETs, Fig. 3 The performance of DSDV protocol

time, because often the rates for packets loss are the same. But AODV has better packet received rate than DSDV.

Emotional contagion; Simulation of crowd emotion

Definitions

Emotional contagion	The emotion of a whole group converges as individuals affect nearby people while the whole group affects the individuals.
Simulation of crowd emotion	Emotion of crowds is simulated by computer algorithms based on personalities of agents, events, and emotional contagion.

Introduction

A crowd is a large group of diverse people gathering closely in the same physical space. Crowds are commonly seen in transportation centers, theaters, shopping malls, and parks. Behaviors of a group are influenced by group emotion which is one of essential factors for modeling realistic groups. *Emotions are an inherent part of group life. Individuals bring their unique emotional tendencies to the group, and the composition and interaction of those emotions produce emotional heat which goes on within, among, and beyond the tendencies of individual members. These group emotions have been viewed as moving from the group level downward (a top-down approach), as well as moving upward from the compositional effects of individual group member emotions (a bottom-up approach)* (Barsade and Gibson 1998). Based on these observations, we can investigate the propagation mechanism of group emotion and then develop techniques to simulate emotion of individuals and crowd. Subsequently, diverse behaviors of crowds induced by different emotion types can be simulated. Crowd simulation techniques have a wide range of applications, such as the layout design of parks, crowd evacuation, crowds in shopping malls, and modeling interaction between pedestrians and vehicles.

To build up a simulation model, we need a model of individuals and a group model. An essential attribute of such models is personality which refers to characteristics of a person that account for consistent patterns of feeling, thinking, and behaving (Cervone and Pervin 2015). In general, a person's personality influences how much the way that he feels; and people influence each other's emotion. A person performs an action based on his current emotion and the received influence. We model a crowd as a set of agents. An agent has many attributes, such as position, velocity, walking speed, desired walking speed, personality, emotion, action, desire, belief, and intention. The agents of a crowd can interact with each other in an environment. An agent's emotions and related behaviors can trigger similar emotions and behaviors of neighboring agents and vice versa. This phenomenon is called emotional contagion (Baig et al. 2014). A simulation technique requires the following items to simulate the emotion of an agent i:

1. An emotion model represents the emotion e of an agent.
2. A personality model represents personality of an agent.
3. A stimulus model represents the stimulus that affects an agent's emotion. The stimulus can be from surrounding agents and the environment.
4. An emotional contagion model represents how the surrounding agents affect each other.

In a simple form, the emotion of agent i can be updated as follows:

$$e_i(t + \Delta t) = e_i(t) + \Delta e_i \Delta t, \qquad (1)$$

where $e_i(t)$ is the current emotion, Δe_i is the emotion change, Δt is the simulation time step, and

$e_i(t + \Delta t)$ is the new emotion. We would like to find a way to determine Δe_i so that the new emotion of agent i can be evaluated. In general, an agent has its own emotion. The neighboring agents and the environment generate a stimulus on the agent. The degree of influence of the stimuli on the agent depends on the agent's personality and perception. Subsequently, the agent changes its emotion over time. At the meantime, the agent also affects the emotions of its neighboring agents. Some agents may be easily influenced by others while some may be able to manage to converge their emotions.

The organization of the rest of entry is as follows. The next section presents personality dimensions and some personality models. Then we present approaches for emotion modeling. After that emotion contagion is presented. Finally, we present some applications and conclude this entry.

Personality Dimensions

Personality psychology studies personality and its variation among individuals. Personality can be encapsulated by certain factors in a continuum. Studies show that a certain set of words can be used to describe aspects of personality to the same person. Factor analysis, which is a fundamental tool in statistics, uses a small set of unobserved variables called factors to describe variability among observed variables. The observed variables are modeled as linear combinations of the factors. Every individual has his own personality that can be represented by many words. Among such words, some of them are dominant and thus we can use fewer words to represent the individual personality.

One of the fundamental problems of personality psychology is identifying the major dimensions of personality variation. We need a representative sampling of the universe of those variables to construct the structure of personality characteristics. The psycholexical approach can be adopted to produce such representative samples. The psycholexical approach is emerged from personal psychology (De Raad 2000), which has two postulates about personality characteristics (Widiger 2017):

1. The important personality characteristics of a group will become a part of the group language.
2. More important personality characteristics are more likely to be represented as a single word (or term) in the language.

By applying the principles of the psycholexical approach, we can group words with similar meanings and then obtain models with a few factors for describing people. Some five-factor models are selected as representatives among all the models. Five-factor models represent the personality of people based on five dimensions. In this entry, we present several five-factor models and the Hexaco model with six dimensions (Lee and Ashton 2013). In personality psychology literature, different personality models (with more dimensions) have been proposed for incorporating more common dimensions for accounting individual difference. Due to richness of human individuality and evolving life habits, the personality models can be changed over time.

The OCEAN Model (Big Five Personality Traits)

The OCEAN model, which is a five-factor model (Fig. 1), has five personality traits. We denote the

Simulation of Emotional Crowd and Applications, Fig. 1 The OCEAN model

five factors of the OCEAN model as $\{\psi^O, \psi^{\mathbf{C}}, \psi^E, \psi^A, \psi^N\}$. The value of each factor is inside [0, 1], in general. The five factors and their traits are listed as follows (Barrick and Mount 1991):

1. Openness to experience (ψ^O): Inventive/Curious vs. Consistent/Cautious
   Traits: Being imaginative, cultured, curious, original, broad-minded, intelligent, and artistically sensitive
2. Conscientiousness (ψ^C): Efficient/Organized vs. Easy-going/Careless
   Traits: Reflecting dependability; that is, being careful, thorough, responsible, organized, and planful
3. Extraversion (ψ^E): Outgoing/Energetic vs. Solitary/Reserved
   Traits: Being sociable, gregarious, assertive, talkative, and active
4. Agreeableness (ψ^A): Friendly/Compassionate vs. Challenging/Detached
   Traits: Being courteous, flexible, trusting, good-natured, cooperative, forgiving, softhearted, and tolerant.
5. Neuroticism (ψ^N): Sensitive/Nervous vs. Secure/Confident
   Traits: Being anxious, depressed, angry, embarrassed, emotional, worried, and insecure.

Besides the OCEAN model, there are different kinds of five-factor models across countries (De Raad 2000). The following lists some examples:

1. The Norman five-factor structure: Extraversion, agreeableness, conscientiousness, emotional stability, culture
2. The American-English five-factor structure: Extravesion/surgency, agreeablness, conscientiousness, emotional stability, and intellect
3. The Dutch five-factor structure: Extravesion, agreeablness, conscientiousness, emotional stability, and intellect
4. The German five-factor structure: Surgency, agreeableness, conscientiousness, emotional stability, and intellect

The HEXACO Model

Lee and Ashton (2013) proposed the HEXACO model of personality as an alternative to the five-factor models. The HEXACO model is constructed based on the cross-cultural research (Ashton et al. 2004) in seven countries, including Dutch, French, German, Hungarian, Italian, Korean, and Polish. The HEXACO model (Fig. 2) has an additional trait Honesty-humility, compared to the Big Five model. Each factor of the HEXACO model has four facets (Ashton and Lee 2009). The six factors and their facets are listed as follows:

1. Honesty-humility: Fairness, greed-avoidance, modesty, sincerity
2. Emotionality: Anxiety, dependence, fearfulness, sentimentality
3. Extraversion: Liveliness, social boldness, social self-esteem, sociability
4. Agreeableness versus anger: Forgiveness, gentleness, flexibility, patience
5. Conscientiousness: Diligence, organization, perfectionism, prudence
6. Openness to experience: Aesthetic appreciation, creativity, inquisitiveness, unconventionality

Simulation of Emotional Crowd and Applications, Fig. 2 The HEXACO model

Although the five-factor and Hexaco models are simple, they have undesirable features. For example, Ashton (Ashton and Lee 2009) commented on three undesirable features in the HEXACO60 model. First, the scales' inter-item correlations or internal consistency reliabilities may not be high. Second, each of the scales may not be unidimensional. Third, the facets in each trait are not expected to define their intended factors univocally. The facets may have nontrivial secondary loadings.

Emotion Models

Ortony et al. proposed an OCC (Ortony, Clore and Collins) model (Ortony et al. 1990) which states that the emotions are valanced reactions to events, agents, and objects. These events, agents, and objects can be either pleasing or displeasing to the subject under consideration. The OCC model classifies 22 different emotions by evaluating (1) consequences of events (happy or unhappy), (2) aspects of objects (like or dislike), and (3) actions of agents (approve or disapprove).

A bipolar circumplex model represents emotion in a two-dimensional (2D) spatial domain, such as the valence-arousal model proposed by Russell (1980). The Russell's valence-arousal model has two orthogonal axes. The vertical and horizontal axes represent arousal and the degree of valance, respectively. Valence reflects the degree of the response from positive to negative (or *pleasant* to *unpleasant).* Arousal indicates the level of activities associated with the emotional response between two extremes which are very *excited* and very *calm* (or *sleepys).* The Russell's model can present a variety of emotions based on the combinations of positive/negative and passive/active pairs (Li et al. 2013). For example, we have the following four types of emotions:

1. Positive-active emotions: Examples are *excited, happy, hope,* and *interested.*
2. Positive passive emotions: Examples are *relaxed, calm, content,* and *satisfied.*
3. Negative-active emotions: Examples are *angry, frustrated,* and *irritated.*
4. Negative-passive emotions: Examples are *bored, fatigue, sadness,* and *tired.*

The PAD model (Mehrabian 1996), which has three dimensions, is a general framework for describing and measuring individual differences in temperament. In general, an individual reacts to the world based on his/her personality traits that constitute one's temperament. The meanings of the three dimensions are as follows:

1. Valence (quality): Unpleasant to pleasant. Valence represents positive or negative affective states.
2. Arousal (quantity): Calm to excited. Arousal indicates the mental and/or physical activity level.
3. Dominance (control): Weak to strong. Dominance indicates the ability for controlling over others or situations.

Intelligent Agent Modeling

Rao and Georgeff (1991) proposed a BDI-architecture which has three attributes: belief, desire, and intention. The emotion of agents affects the desires, decision and action of the agents.

1. Beliefs represent the cognitive information that an agent has about a virtual environment. The cognitive information includes the data describing environmental characteristics and other nearby agents.
2. Desire indicates the initial motivation of an agent. In other words, it is the state that the agent wants to accomplish. The agent has certain desires under specific situations.
3. Intention indicates the current action that an agent intends to take so that the agent can accomplish its own desire.

The BDI architecture can solve the problem of agents' goal programming and decision making. We can integrate the three models, PAD, personality (e.g., OCEAN), and BDI, to simulate diverse behaviors of agents in public emergency (Mao

et al. 2019). The beliefs, desires, and intention of an agent can be affected by the emotion of the agent.

Crowd Types, Emotion, and Action

We can classify crowd situations based on the presence of an event and the level of interactions in crowds. In general, event and nonevent crowds are the two most common situations (Li et al. 2013). People of an event crowd want to interact with each other in performances or activities, such as concerts, conferences, church gatherings, and parties. However, people of a nonevent crowd want to achieve an external goal or to obtain benefits in joining the crowd. Nonevent crowds do not take part in any activities or performances.

Studies show that crowd with certain kinds of emotions tend to perform certain actions (Li et al. 2014). The study reveals that there is an association between emotional feelings and actions. The study employed a set of 13 crowd emotional feelings, including six positive and seven negative ones, and investigated the corresponding action tendencies (Frijda et al. 1989). The actions include *be with, protection, attending, avoidance,* and *rest.* The study reports that, in general, people do not have any action tendencies when they feel positive in event crowds. Furthermore, negative action tendencies are not linked with negative emotional feelings.

Modeling Emotional Crowds

We can simulate socially emotional crowds based on an emotion network structure (Lyu and Zhang 2018). In the emotion network structure, a network node and a relationship arc represent an individual emotion space and a psychological linkage, respectively. Furthermore, an emotion tree represents an emotionally homogeneous crowd. Initially, each crowd is modeled as an emotion tree which has an emotion component that is evaluated to be a value (scalar or a vector). Therefore, we can determine the psychological distance between the emotion trees of every two individual crowds. The agents in an emotion tree have similar emotion and they often tend to interact with one another. While the agents in a crowd or crowds interact with each other, the emotions of the agents can change gradually due to their diverse personality characteristics. Hence, the relational distributions of the agents change over time. Subsequently, the agents move between different subgroups while they interact with each other in a long time period. Of course, if two crowds exhibit similar emotion, they can be merged.

A traditional system for simulating the emotion of an agent has two layers, a physical layer ($\mathbf{L}_\mathrm{P}$) and a decision layer ($\mathbf{L}_\mathrm{D}$). The functions of the two layers are as follows:

1. The physical layer handles navigation, collision prevention, interaction with others, and motion execution.
2. The decision layer collects and processes data around the agent. It also performs data analysis and decision making.

The physical layer is defined as follows:

$$\mathbf{L}_P = \left\{ \Phi_{phy}, \Psi_{env} \right\}, \tag{2}$$

where Φ_{phy} is a dynamic structure that is relevant to crowds and contains a set of physical states about the environment, including agents and movable regions; and Ψ_{env} is a structure that represents the states of geometric entities and paths in an environment.

The decision layer $\mathbf{L}_\mathrm{D}$ depends on the environment information, such as agents and other objects. The crowds may have some initial targets Ω_{tar} that depend on the intentional states of crowds, Φ_{int}. Furthermore, the crowds can be affected by environmental events Ψ_{eve} and the physical environment information collected by $\mathbf{L}_\mathrm{P}$. These two factors Ψ_{eve} and $\mathbf{L}_\mathrm{P}$ are considered when crowds make the movement decisions in a dynamic manner. Therefore, we define $\mathbf{L}_\mathrm{D}$ as follows:

$$\mathbf{L}_D = \{ \Omega_{tar}, \Phi_{int}, |\mathbf{L}_P \}. \tag{3}$$

Finally, we denote Φ_{emo} as the set of crowd emotional states and define the emotion layer ($\mathbf{L}_\mathrm{E}$) as follows:

$$\mathbf{L}_E = \{\Phi_{emo} | \mathbf{L}_P, \mathbf{L}_D\}. \quad (4)$$

$\mathbf{L}_E$ depends on both layers $\mathbf{L}_P$ and $\mathbf{L}_D$. In general, an agent collects data from the environment and analyzes the data to make decision while the agent moves to its target. However, the environment may change in a dynamic manner and thus the emotion of the agent can be affected by other agents and events in the environment. Subsequently, the agents change its decisions and perform appropriate actions from time to time. To summarize, the simulation process has the following steps:

1. We invoke the emotion layer $\mathbf{L}_E$ to update the emotion states of crowd. The emotion layer handles the emotion contagion process in a dynamic manner.
2. $\mathbf{L}_D$ is invoked for agents to collect external information, including the environment information, nearby agents, and surrounding objects. Then it analyzes the internal intentions of the agents. Finally, it decides the targets and actions of crowd.
3. The decision layer $\mathbf{L}_D$ send decisions to the physical layer $\mathbf{L}_P$. The physical layer determines the feasible paths based on the geometric information. While agents are moving to target positions, $\mathbf{L}_D$ performs collision avoidance for them. Because the environment is changed in a dynamic manner, the paths for the agents are updated accordingly.

In the decision layer $\mathbf{L}_D$, the function *update* computes the new velocities of agents $\mathbf{v}_d$. We consider several factors in updating the decisions for a crowd, including (1) the emotion-controlled velocity of agents $\mathbf{v}_e$, (2) an algorithm of a finite state machine Γ_{fsm}, and (3) an algorithm for navigation Γ_{nav}. The finite state machine Γ_{fsm} traces the states of the agents and can be used for determining the decisions of the agents. The navigation algorithm Γ_{nav} computes the optimal paths for the agents based on the agent decisions. Formally, the prototype of the function is defined as follows:

$$\mathbf{v}_d \leftarrow \mathbf{L}_D.update\left(\mathbf{v}_e, \Omega_{int}, \Phi_{phy}, \Psi_{env}, \Psi_{eve}, \Gamma_{fsm}, \Gamma_{nav}\right). \quad (5)$$

Note that the decision layer $\mathbf{L}_D$ does not consider the physical environment thoroughly when a decision is made. Thus, an agent may move in a direction that leads to collision. Thus, we need to rely on the physical layer to adjust $\boldsymbol{v}_d$ properly. We employ the physical layer to compute the final velocities of the agents. In this sense, an algorithm Γ_{col} for collision avoidance is required while the agents are moving in the environment. Formally, the prototype of the *update* function in $\mathbf{L}_P$ is defined as follows:

$$\mathbf{v}_p \leftarrow \mathbf{L}_P.update\left(\mathbf{v}_d, \Phi_{phy}, \Psi_{env}, \Gamma_{col}\right). \quad (6)$$

While the agents interact with each other, their emotions change over time. The agents may come together if their emotions are similar to each other. Therefore, we can use emotion trees to manage the agents with similar or dissimilar emotions. Furthermore, we employ the emotion trees to perform interaction between groups.

Thus, an emotion tree encapsulates the emotion propagation among individuals in groups. We consider the following factors to build an emotion tree for a group:

1. An emotion tree should encapsulate the internal emotion values of a group, denoted as δ_{int}. Thus, we can use such internal values to identify the group. The internal values include the threshold of emotion energy, the interaction period related to emotions of the group, and the overall emotions of the tree.
2. The group has a set of members, denoted as ϕ.
3. The group has a representative that is the root of group *root*. The root has several functions that be easily extracted in simulation. For example, the root can be the center, goal, or target of the group.
4. Emotions of the group can give impact to the other groups in a nearby region. We denote δ_{emo} as the group emotion values that can influence other groups. The set of values include emotion concentration levels, density, and the covered region.
5. The members of the group move in a spatial domain. Thus, they are bounded inside a region which has the minimum area. The region has a boundary Ω that encloses all the

members. Because the members are moving, the shape of the region changes. Therefore, the boundary Ω deforms over time.

6. We need a database M_o of action clips that are labeled for various types of emotions and behaviors. Thus, we can use an action clip to animate an agent accordingly.

Formally, we define an emotion tree as follows:

$$\mathbf{T}_E = \{\delta_{int}, \delta_{emo}, root, \phi, \Omega, M_o\}. \quad (7)$$

An emotion tree has a set of relationship arcs connecting agents. Relationship arcs are psychological links which are used for modeling emotion propagations of agents. The individual emotion model represents an agent's emotion and consists of three components: an emotion space (E), personality (p), and an emotional command space (C) which is constructed based on emotion rules. The emotion space is represented as the wheel of motion which has four pairs of opposing basic dimensions (Plutchik 2001). The four basic dimensions are: *surprise-interest, sadness-happiness, fear-anger,* and *disgust-trust.* In general, an agent performs a certain action which is selected from M_o based on its current emotion.

Contagion of Panic Emotion in Multihazard Environments

We employ crowd emotion to simulate the micro-level behavior of crowd in multihazard environments (Xu et al. 2019). We report the method proposed by Xu et al. as follows.

We classify hazards into six types based on three attributes as follows.

1. Durations: How long does a hazard last?
   a. A transient hazard: Individuals are threatened for a short period when the hazard occurs. After the hazard disappears, the individuals are no longer affected by it.
   b. A persistent hazard: Individuals are threatened for a long period when the hazard occurs. Furthermore, the hazard continues to affect the individuals in the area around it over its life time.

   A crowd and individuals can change adversely their psychological states when they encounter these two types of hazards. They must respond immediately to escape from such dangerous areas.
2. Time of occurrence (generation time): When do the hazards occur?
   a. Concurrent hazards: Individuals are affected concurrently by two or more hazards during the same period. The influences of the hazards can be treated as a single hazard and their impacts are accumulated.
   b. Nonconcurrent hazards: Individuals are affected by the hazards individually. Furthermore, the effects of a new hazard influence the agents in an accumulative manner. In other words, the agents can receive multiple impacts of different types from hazards of various types.
3. Dynamics or mobility: Does a hazard change its position or the influence area?

   A hazard has two main attributes, position and influence region.
   a. Static hazards: Their positions and influence regions do not change.
   b. Dynamic hazards: A dynamic hazard has at least one attribute which is changed over time. Therefore, the position and influence area of such a hazard must be determined in a dynamic manner over a time horizon.

   The hazards make their influence regions become dangerous. Furthermore, they have great impacts on the emotions and decision making of a crowd. Consequently, the movement of the entire crowd is affected. The agents tend to move to safe regions when hazards occur. When the physical and decision layers update paths and crowd emotions, the hazards must be considered.

Several close hazards occur in a finite time horizon and form a dangerous field. They give direct impacts on the nearby agents when they occur. We can use a function which converses the intensity of danger induced by these hazards to panic emotion. Furthermore, in the influence

region of the hazards, the agents affect each other and panic emotion propagates among themselves. The process of the emotion propagation among the agents can be simulated based on an emotional contagion model (ECM). Mainly, the emotional contagion model computes how the emotion of an individual agent affects other agents (bottom-up) and how the emotion of a group affects individual agents (top-down). It requires several essential factors to compute the panic emotion of an agent. For example, the factors include the following: (1) the distance between a hazard and the agent; (2) the personality of the agent; (3) the nearby agents of the agent; (4) the distance between the agent and the nearby agents.

A hazard s covers a finite region A_s called dangerous range with a boundary γ_s. It has an influence radius, r_s. In the case that the hazard s is dynamic, its area grows and its position can move over time. Furthermore, the hazard s generates a field of danger over a time horizon U (i.e., a time duration). We assume that the strength of danger, $\Gamma_s(\mathbf{q}, t)$, at the position $\mathbf{q}$ can be evaluated at time t. $\Gamma_s(\mathbf{q}, t)$ is a constant inside the hazard area but becomes smaller for a larger distance. Formally, we have

$$\Gamma_s(\mathbf{q},t) = \begin{cases} 1 & \text{if } \mathbf{q}\in A_s, \text{ and } t\in U \\ \frac{1}{\sqrt{2\pi}\cdot r_s} e^{-\frac{(\mathbf{q}-\mathbf{q}^\gamma)^2}{2r_s^2}} & \text{if } \mathbf{q}\notin A_s, \left\|\mathbf{q}-\mathbf{q}^\gamma\right\| < r_s, \text{ and } t\in U \\ 0 & \text{otherwise.} \end{cases}$$

Here, $\mathbf{q}^\gamma$ ($\in \gamma_s$) is on γ_s and closest to $\mathbf{q}$. The strength of danger affects how quickly the panic emotion of an affected agent grows.

Denote H as the set of all the hazards, that is, $H = \{h_1, h_2, \cdots, h_n\}$. We accumulate the strengths of danger of the hazards which affect an agent i to compute the panic value of the agent. The panic value $E_i^h(\mathbf{q}, t)$ of agent i is computed as follows:

$$E_i^h(\mathbf{q},t) = \sum_{s\in H} \Gamma_s(\mathbf{q},t). \tag{8}$$

Besides hazards, an agent's personality and nearby visible agents affect the decision making of the agent. The personality of the agent has impacts on how fast the agent influences other agents and vice versa. On the one hand, the agent has an ability to express the degree of peril to one another. On the other hand, other nearby agents also influence the agent by a certain amount. In these two cases, we use two thresholds, expressiveness (e^{T_i}) and susceptibility (s^{T_i}), for checking whether the agent delivers successfully the hazard warning to others and being affected by others, respectively. Thus, the agent warns successfully to the other agents if its emotional value higher than its expressiveness threshold. Similarly, if the emotion value of the agent i is larger than s^{T_i}, the agent is affected by the other agents. The two thresholds are computed as follows:

$$e^{T_i} \sim N\left(0.5 - 0.5\psi_i^E, \left((0.5 - 0.5\psi_i^E)/10\right)^2\right), \tag{9}$$

and

$$s^{T_i} \sim N\left(0.5 - 0.5\varepsilon_i, \left((0.5 - 0.5\varepsilon_i)/10\right)^2\right), \tag{10}$$

where N(·,·) represents a normal distribution with the first parameter as the mean and the second parameter as the standard deviation; $\varepsilon_i (\in [-1, 1])$ is the empathy value for agent i. Denote $M_P = \{O,C,E,A,N\}$. We can compute the empathy value based on the OCEAN model. Formally, we have.

$$\varepsilon_i = \sum_{j\in M_P} c^j \psi^j, \tag{11}$$

where $c^O = 0.354$, $c^C = 0.177$, $c^E = 0.135$, $c^A = 0.312$, and $c^N = 0.021$ (Jolliffe and Farrington 2006).

Denote V (i) as the set of agents in the perceived range of agent i. We compute the effect caused by all the agents j ∈ V(i) as follows:

$$E_t^c(P,t) = \sum_{t'=t-k+1}^{t} \sum_{j=1}^{n} d_i(t') E_j^{c'}(P_j, t'), \tag{12}$$

S

where $d_i(t') \sim N(0.1,0.0001)$ is the dose value which agent i received from agent j at time t; $E_j^c(P_j,t)$ is the panic emotion of agent j ∈ V(i) at time t. The value of k is the duration for emotional accumulation of agent i at time t.

The panic emotion of individuals decays gradually to the normal state. This process can be formulated by using an emotional attenuation function. Denote η as the emotional decay rate and $\mathbf{q}^{\text{pre}}$ the position at the previous time step. Thus, the new panic of agent i is computed as:

$$E_i^d(\mathbf{q},t) = E_i(\mathbf{q}^{pre},t-1)\cdot\eta, \eta\in(0,1]. \quad (13)$$

The total panic emotion of agent i at position $\mathbf{q}$ is computed by.

$$\Delta E_i(\mathbf{q},t) = E_i^h(\mathbf{q},t) + E_i^c(\mathbf{q},t) - E_i^d(\mathbf{q},t) \quad (14)$$

$$E_i(\mathbf{q},t) = E_i(\mathbf{q}^{pre},t-1) + \Delta E_i(\mathbf{q},t) \quad (15)$$

We can determine the stressful behaviors of the agents after all the agents are processed. Denote $\mathbf{q}$ and $\mathbf{v}_i^s$ as the position and velocity of an agent, respectively. When the agent is affected by a hazard s at position $\mathbf{q}_s$, it attempts to follow a safety direction $\mathbf{u}$ (i.e., along $\mathbf{q}^\gamma - \mathbf{q}_s$) to escape, where $\mathbf{q}^\gamma$ is a point on γ_s and closest to the agent. Of course, if the agent is not inside the impacted area of any hazard, it moves along its desired direction $\mathbf{v}_i$. Thus, we can determine the expected movement direction of the agent under multihazards as follows:

$$\mathbf{v}_i^s(\mathbf{q},t) = \begin{cases} \Sigma_{s=0}^{n-1}\Gamma_s(\mathbf{q},t)\cdot\mathbf{u} & \text{if } \left\|\mathbf{q}-\mathbf{q}_s\right\| < r_s \quad \text{and } t\in U \\ \mathbf{v}_i & \text{otherwise.} \end{cases}$$

Assume that the probabilities of agent i following its desired direction and others' directions are p, and $1-p$, respectively. Thus, we can determine the final movement direction of the agent as follows:

$$\mathbf{v}_i^c(\mathbf{q},t) = E_i(p,t)\mathbf{v}_i^s(\mathbf{q},t) + (1-E_i(\mathbf{q},t))\sum_{j\in R(i)}\mathbf{v}_j^c\left(\mathbf{q}_j,t\right), \quad (16)$$

where $\mathbf{v}_i^c(\mathbf{q},t)$ represents the moving direction of agent i at position $\mathbf{q}$ at time t; *R(i)* is the set of neighboring visible agents of agent i. On the right side of the equation, the velocities of the agents under the hazard impact cannot be determined. We can initially set those velocities of the agents by using Eq. 15. And then we perform Eq. 16 for a few times to determine the final velocities of the agents.

Each agent has a desired movement direction. However, if the agent is affected by external factors such as hazards and nearby agents, the agent has to determine its final direction. Furthermore, the agent should consider the appropriate global paths for moving to a target while collision avoidance is achieved. To locally determine the final movement direction of agents, we can adopt the navigation algorithms, such as reciprocal velocity obstacle (RVO) (Van den Berg et al. 2008), radial view based method (Wong 2016), vision-based method (Dutra et al. 2017), and predefined evacuation routes (Wong et al. 2017).

Applications

Emotional group simulation can be applied to a wide range of domains to enrich the realism of virtual agents, such as simulation of rare pedestrians behaviors, self-driving learning systems, pedestrian trajectory prediction, terrorist attacks, and crowd evacuation. The decision making of agents is affected by its personality, the surrounding agents, dynamic objects, and environments. We give some application examples as follows.

Mao et al. (2019) present an emotion-based diversity behavior model, by adopting the OCEAN personality model and the OCC emotion model. Their method is integrated with a CA-SIRS emotion contagion model. The model considers the effects of YerkesDodson Law on individuals behaviors, which allows individuals to make behaviors under stressful circumstances. The model can provide diverse individual behaviors, including simulation of pedestrians crossing roads, and terrorist attacks.

Zhang et al. (2017) present an approach for maximizing positive emotional contagion in

crowd evacuation. Safety officers have positive emotions and can calm the crowd down, thereby reducing serious accidents. The approach is as follows:

1. A computational model of positive emotional contagion evaluates how safety officers calm a crowd down. To do so, a trust-based emotional contagion network (T-ECN) and a model of heterogeneous emotional contagion are proposed to manipulate the individual trust relationships and factors for emotional contagion, respectively.
2. A maximization problem of emotional contagion is formulated for agents (including safety officers). The maximization problem is an NP-hard problem. Thus, the optimal positions of safety officers are determined based on an optimization algorithm, such as artificial bee colony.

The T-ECN G(V, *E*) is a directed graph. Each node v ∈ V represents an individual in the crowd. Each directed edge $e(i, j) \in E$ connects node *i* to node *j* and denotes that *j* trusts *i*. An agent *i* is affected by agent *j* when *j* is visible for *i*. The approach formulation for neighboring agents is quite similar to the contagion model. To model how agents affect each other and how a group affects individuals, we should formulate how the agents are linked to each other. After that we can employ optimization techniques to maximize or minimize an objective function. For example, we can place safety officers at proper positions to minimize the overall evacuation time of agents.

We can simulate agents moving in multihazard environments (Xu et al. 2019), such as crowd evacuation in office buildings or regions with terrorist attacks, and pedestrians crossing crossroads with multiple vehicles. The agents affect each other their emotions and decision making.

Conclusion

This entry covers topics on personality, emotion, emotion contagion, personality models, and the applications of simulation techniques on emotional crowd. In general, a crowd simulation system has a physical layer and a decision layer. The physical layer provides information for agents to make proper decision in the decision layer. We also present an approach for modeling emotion contagion in a crowd. It is important to collect neighboring agents of an agent so that we can determine how the agent is affected. The degree of emotion influence on an agent depends on the agent's personality and the surrounding environment. The action taken by an agent can be computed based on the BDI model. Emotional crowd enriches crowd behaviors and has a wide range of applications in games, movies, and disaster simulation. Emotional crowds have been adopted in evaluating task performance of users in virtual reality (Huang and Wong 2018; Volonte et al. 2020).

Definition

Sketch-based posing refers to the automatic posing of 3D models using 2D hand-drawn sketches. It also refers to user interfaces that allow for 3D posing by drawing, instead of operating complex 3D software controls.

Introduction

Animation encompasses entertainment ranging from traditional hand-drawn pieces like *Snow White and the Seven Dwarfs* all the way to cutting-edge visual effects in blockbuster Hollywood films like *Avengers*: *Age of Ultron*. As the boundaries of what is possible are pushed and 3D computer animation is widely adopted, this originally artistic field has become highly technical. Today's animators employ cutting-edge techniques, such as 3D skeleton manipulation and mocap.

This technological boost has helped artists give life to characters and worlds that previously existed only in the realm of imagination. Unfortunately, it has also increased the breadth of knowledge a modern animator is required to have. Classically trained animators may find it even more difficult to transfer their skills to 3D computer animation. To address this issue, researchers have attempted to combine technology with traditional methods. An example of these attempts is to use physical, modular components to build puppets which are then used to animate 3D models (Jacobson et al. 2014). Another example is leveraging the pencil-and-paper skills of traditional animators.

This chapter is an overview of the latter: methods that utilize hand-drawn sketches in order to pose or animate 3D models.

Background

In traditional 2D animation, the artist is drawing the shape of the character while also drawing the movement of the character, conveying very dynamic movement using the 12 principles of animation (Thomas and Johnston 1984). In 3D animation, the shape of the character already exists in the form of a 3D model, and the artist has to deform it using 3D software like Autodesk Maya.

Keyframing is the mainstream method of animating 3D characters, by moving controls on a hierarchical structure, called a rig (e.g., joints on a skeleton). Forward kinematics (Burtnyk and Wein 1976) allow the artist to control the pose by *rotating* joints of the rig. Inverse kinematics (IK) (Zhao and Badler 1994) allow the artist to *translate* joints (e.g., the wrist) of a character to a position in 3D space, and the rest of the body follows to fit a pose.

A 3D rigged model is still the basis for all the methods that are presented in this chapter. The novel aspects of these methods are not in how a 3D character is modeled or rigged, but in how a user can manipulate the character's rig, replacing the mainstream skeleton manipulation process with a sketch-based one.

The first category of sketch-based approaches for 3D animation consists of supervised methods, where a user guides the system through hand-

drawn sketches instead of, e.g., using a mouse. Examples of this *sketch-based interface approach* attempt to extract animated sequences from mocap databases (Xiao et al. 2015) or make use of differential blending for expressive poses (Oztireli et al. 2013).

The second category of methods does not use hand-drawn sketches as an interactive interface but as a way to automatically infer the 3D pose. This category can be further broken down into two subcategories, the *database approach* and the *generative approach*. The database approach uses a database as a knowledge domain, whether it is to position objects in a scene (Xu et al. 2013) or to classify the shape itself (Eitz et al. 2012). The generative approach attempts to pose a pre-existing 3D model until the pose matches the information from the drawing, whether it is to pose animals (Favreau et al. 2006) or humans (Ivekovic et al. 2008).

Common Issues

Posing 3D models from 2D drawings is a complex, open problem which has many commonalities with the original computer vision problem of inferring a 3D pose from 2D images (Gavrila 1999). The problem is therefore under-constrained, as the 2D drawings do not contain sufficient information to extrapolate accurate 3D pose data.

The computer vision problem deals primarily with real photographs, while computer animation is full of fantastic creatures. The anatomical limits of imaginary creatures are often unknown, unlike those of humans. Moreover, a sketch can lack color or contain noise (e.g., in the form of shading). As exaggeration is often used to add dynamism, sketches can be inaccurate in terms of scale.

When dealing with photographic or video data, multiple cameras positioned around the subject can be used to provide multiple viewpoints. For example, it is possible to have a room with cameras on all walls, so that when a person steps in, they are viewed from multiple angles. In contrast, a hand-drawn animation frame would only be drawn with one view angle in mind.

Finally, the *forward-backward* or *depth ambiguity* is a recurring issue. For specific poses, it is difficult to know if a limb is facing forward (toward the camera) or backward (away from the camera). For example, given only the silhouette of a drawn lamp, more than one interpretation exists: the lamp's head could be facing the camera or away from the camera (Fig. 1).

State-of-the-Art Work

In this chapter, three pieces of recent research are singled out and explained in more detail. As an example of the *sketch-based interface approach*, the line of action is used as a user-friendly interface for posing of 3D characters (Guay et al. 2013). Using drawings and minimal user input, a *database approach* example leverages a set of mocap animation sequences to use as a knowledge base (Jain et al. 2009). Finally, an

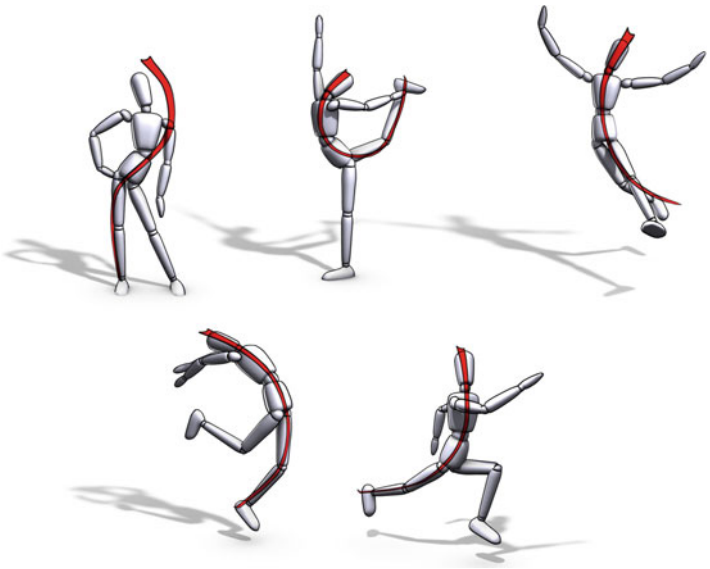
Sketch-Based Posing for 3D Animation, Fig. 1 Example of the depth ambiguity issue in the inferred 3D pose of a lamp

example of the *generative approach* uses global optimization and generates new poses every iteration, until the correct pose is found (Gouvatsos et al. 2014).

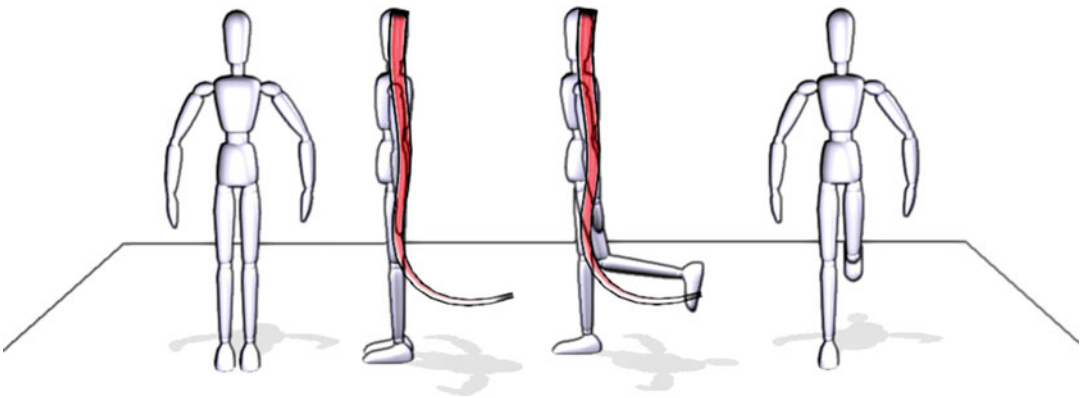
Sketch-Based Interface Approach

The line of action (LOA) is a tool used by animators that helps capture the principal shape and expression of a character in a single line (Fig. 2). These lines are C- or S-shaped 2D curves. In their work, Guay et al. propose a mathematical definition of the LOA. By formulating and solving an optimization problem, they are able to align a 3D character's bones to lines of action that are drawn by the user. The user can view a 3D character from different angles and draw curves on top. For example, a user who wanted to bend a 3D character's knee would look at the character from the side and draw a C-shaped curve, indicating a bent leg (Fig. 3).

The LOA is used to determine the screen space positions and tangents of a subset of the 3D character's bones, which Guay et al. call the body line. The body line is defined as a maximal, connected



Sketch-Based Posing for 3D Animation, Fig. 2 Character poses created by sketching lines of action (Guay et al. 2013)



Sketch-Based Posing for 3D Animation, Fig. 3 Bone rotations are constrained to the viewing plane. The bones are parameterized as a single axis-angle component. The axis is the camera's viewing direction projected onto the floor plane. From left to right is the initial pose, a side view with the LOA, the result after optimization, and a frontal view of the final pose (Guay et al. 2013)

Sketch-Based Posing for 3D Animation, Table 1 Number of strokes and rotations and time taken using lines of action versus using 3D IK widgets in Maya (Guay et al. 2013)

Figure	Num. of strokes and rotations	Time (LOA)	Time (Maya)
Walk	4 strokes 1 rotation	20 s	90 s
S shape	3 strokes 0 rotations	20 s	120 s
Hero punched	6 strokes 2 rotations	90 s	150 s
Hero punch	7 strokes 4 rotations	2 min	3 min 30 s
Animation			
Dancers	6 strokes 1 rotation	30 s	2 min 45 s
Cartoon swing	7 strokes 1 rotation	45 s	2 min 30 s
Muybridge	34 strokes 1 rotation	6 min	22 min

linear chain in a character's skeleton, for example, from head to a foot or from a hand to a foot. As such, a total of ten body lines exists by this definition. The user can manually select the body line they want to manipulate, or they can draw an LOA to select the body line automatically. Once a body line is selected, the best pose is found by solving an energy minimization problem. The difference between the shape of the character's bones in the body line and the shape of the LOA is minimized, using gradient-based local optimization.

The evaluation compares the time it takes to recreate poses with the method by Guay et al. versus the time it takes to recreate the poses with inverse kinematics in Autodesk Maya (Table 1).

Database Approach for Automatic 3D Posing and Animation

The work by Jain et al. introduces an algorithm which takes a set of 2D hand-drawn frames as input. Additionally, a user overlays joints (as dots) on top of the frames and specifies the position of an orthographic camera in 3D space. The algorithm maps the input to a database of mocap information to identify a suitable clip. The clip is projected to 2D and matched to the hand-drawn frames in two ways: timing and exact pose. Finally, the 2D time-aligned and posed result is reconstructed in 3D.

Jain et al. propose a novel pose descriptor to represent 2D poses. This pose descriptor allows for pose comparison while being invariant to translation and scale (meaning it is not affected by changes in translation and scale). Each joint is represented as an angle with respect to a coordinate frame attached to its parent joint. For example, a wrist is represented as the angle between the wrist-elbow bone and a coordinate frame attached to the elbow (Fig. 4). Therefore, a given pose P is a vector of polar angles θ_n:

$$P = [\theta_1, \theta_2 \ldots \theta_K],$$

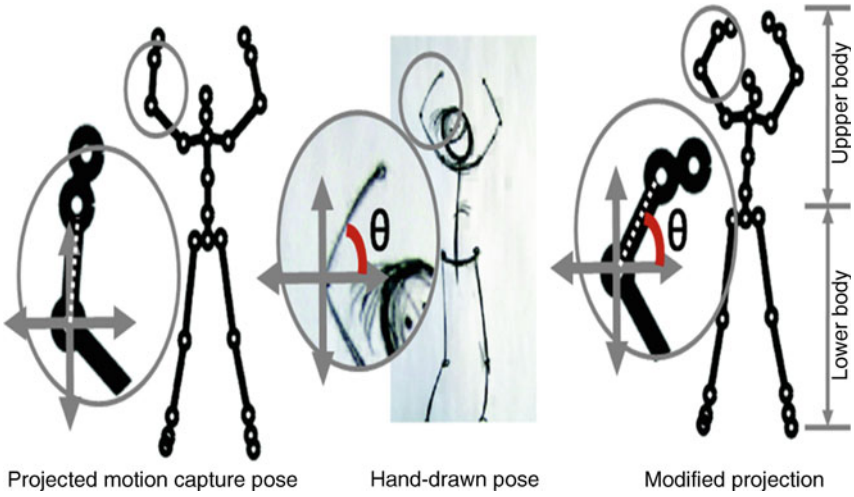
where K is the number of joints pinpointed by the user.

Jain et al. break their algorithm down to three steps. Firstly, the mocap sequence is aligned to the timing of the sketches, using the dynamic time warping algorithm (Sakoe and Chiba 1978). Secondly, the time-aligned mocap segment is projected to 2D and made to best match the pose in the sketches. The 3D projection (projecting a 3D space into 2D) is achieved through the user-specified orthographic camera. To match the pose, each joint is rotated in the image plane until its pose descriptor matches the pose descriptor of the sketch. Thirdly, the missing third dimension is inferred. Jain et al. formulate a linear least squares system to estimate the optimal 3D pose given the time-aligned and fitted 2D pose.

This method is evaluated by animating a ballet dancer, a happy flower, a stylized sneaky walk, and a sequence of jumping jacks (Fig. 5).

Generative Approach for Automatic 3D Posing

Gouvatsos et al. build upon the works of Jain et al. and Ivekovic et al., in order to present a general method for automatically posing 3D



Sketch-Based Posing for 3D Animation, Fig. 4 The pose descriptor consists of in-the-image plane angles for every limb segment (Jain et al. 2009)

models. The proposed method avoids making external assumptions about the 3D model, allowing it to be used on different types of characters (e.g., humans and horses). Similarly with Jain et al., minimal user input is necessary in the form of overlaying the joints over the hand-drawn sketches. Additionally, a camera in 3D space is used to project a 3D pose to 2D. The sketch is compared to a rendered image of the 3D character, using a combination of computer vision descriptors. Different 3D poses are generated and compared until a good match to the sketch is found.

Gouvatsos et al. use three descriptors to compare drawings to renders. The first comparison descriptor is the position of joints overlaid on top of the sketch (Fig. 6). The second descriptor is an edge map extracted with the Canny algorithm (Canny 1986), which represents the internal lines of the drawing (Fig. 7). Finally, the third descriptor is a silhouette of the character, which represents the overall shape (Fig. 8).

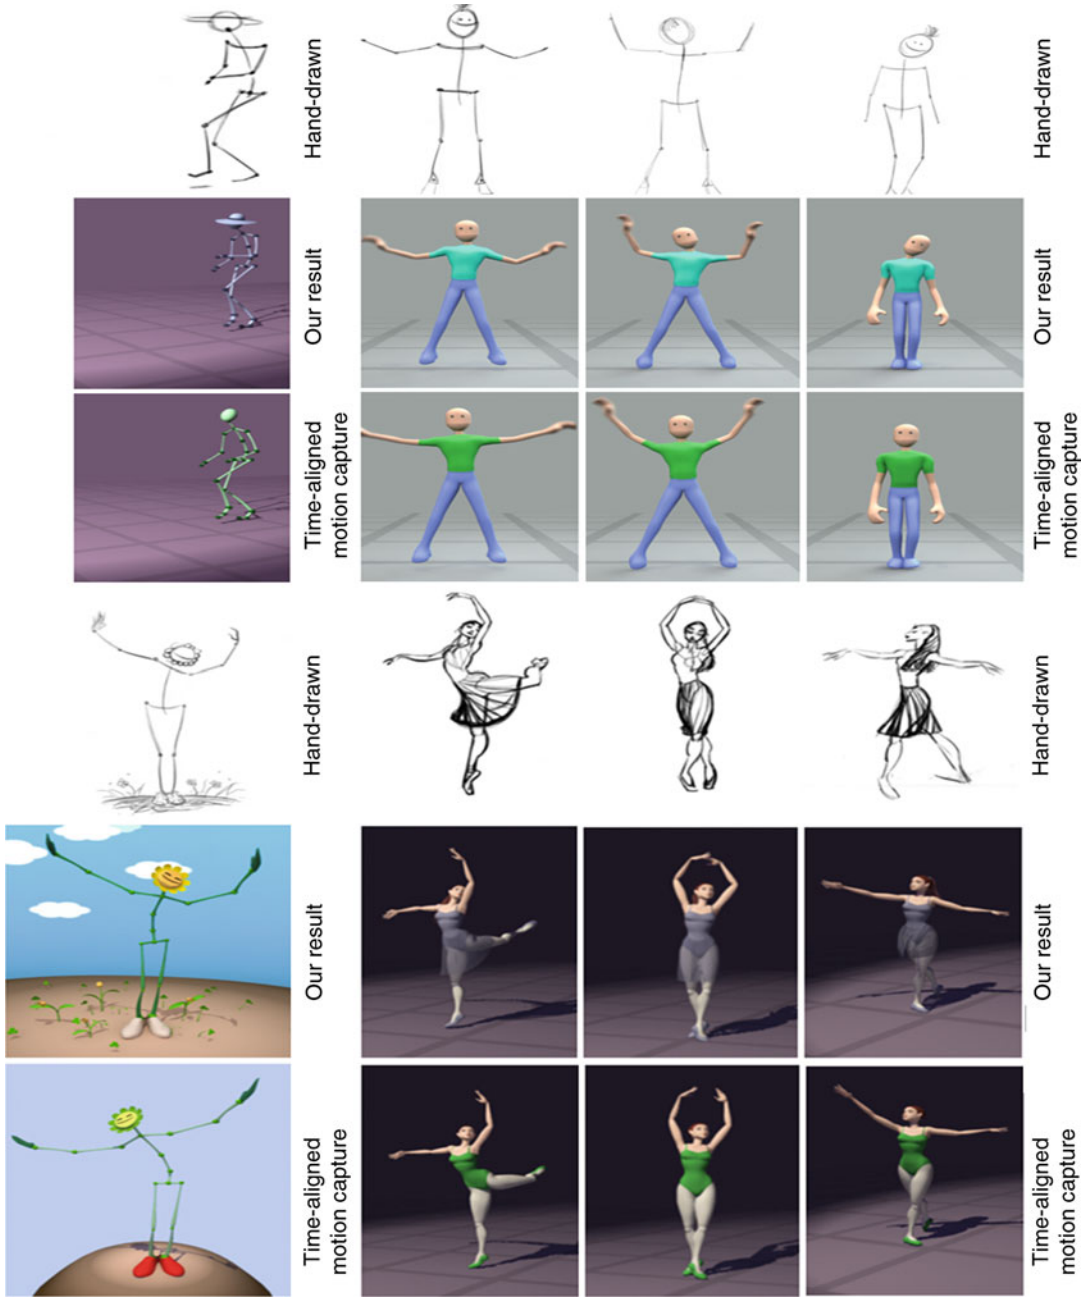
The method proposed is to generate new 3D poses and attempt to minimize the difference between them and the sketch. All the possible poses are seen as a search space of solutions. To navigate that search space, a variation of the particle swarm optimization (PSO) algorithm is used. The difference between the hand-drawn sketch and the 3D pose is represented by an objective function with three terms, one term for each descriptor.

To improve its global search capabilities, the PSO variation is implemented to run on a graphics processing unit. Moreover, a constriction factor and random variation are added in every iteration, to speed up convergence and avoid local minima, respectively.

This method is evaluated by posing a horse (Fig. 9) and a lamp (Fig. 10).

Discussion

Guay et al. present an interesting interface that allows beginners to quickly and intuitively pose 3D characters. However, more detailed, complicated poses are not possible to reconstruct, as the LOA is limited to C- and S-shaped curves. Jain et al. present an automatic posing method that produces impressive results, but the dependence on a mocap database means it is not always an option. Building a database can be expensive, especially for non-humanoid animation. Gouvatsos et al. present an automatic posing method that does not require a database and can be applied to any character. However, it takes



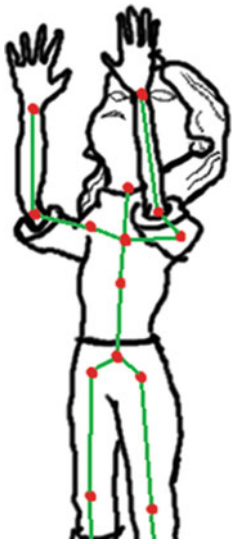
Sketch-Based Posing for 3D Animation, Fig. 5 In all cases, the generated 3D animation matches the hand animation much more closely than the mocap animation (Jain et al. 2009)

longer to run than both other methods and may have less accurate results.

The implementation details of each approach can be studied in the published works. Analyzing them provides insight into patterns that can be used for successful sketch-based 3D posing.

Assuming one is able to formulate a representation for the poses, it is still necessary to match a

Sketch-Based Posing for 3D Animation, Fig. 6 Joints overlaid by a user on top of a drawing



Sketch-Based Posing for 3D Animation, Fig. 8 Silhouette of a drawing

Sketch-Based Posing for 3D Animation, Fig. 7 Edge map of a drawing

3D posed model to the 2D sketch and infer the missing depth. To compare a 3D pose to the 2D sketch, both need to be in the same space. As such, the 3D pose can be reduced to 2D through a camera (e.g., by rendering or using the depth buffer). This camera represents the imaginary camera an artist has in their head when drawing a scene. The missing depth can be inferred through optimization, and all three presented works use an objective function to compare poses.

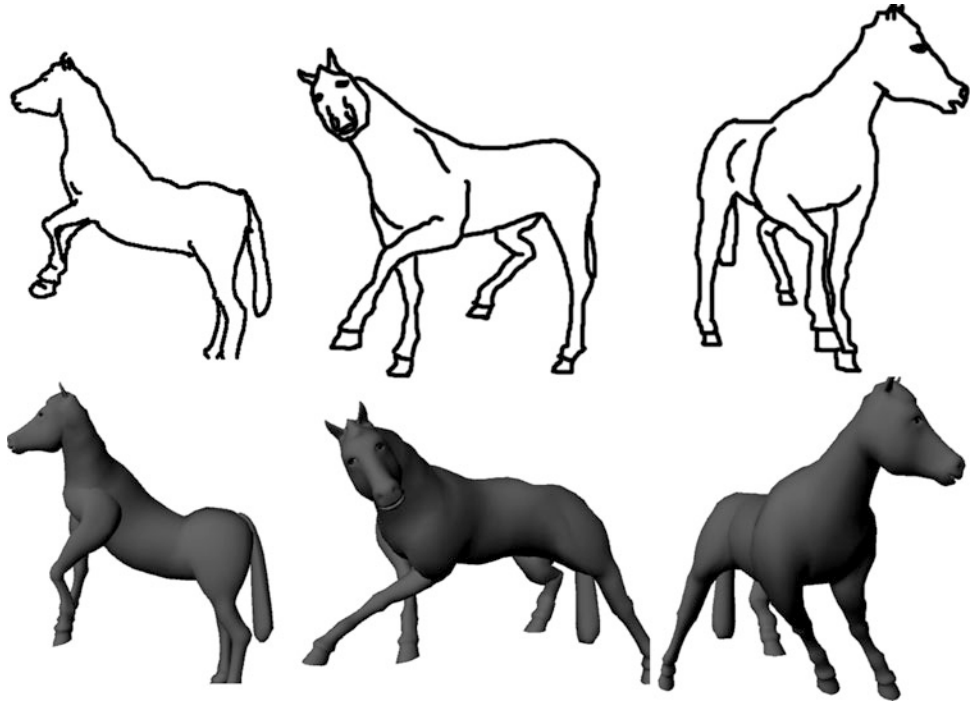
Overall patterns for implementation are deduced by generalizing from the findings of recent works. While these patterns are addressed one by one, they can also be combined depending on the implementer's aim.

Representing and Comparing Poses

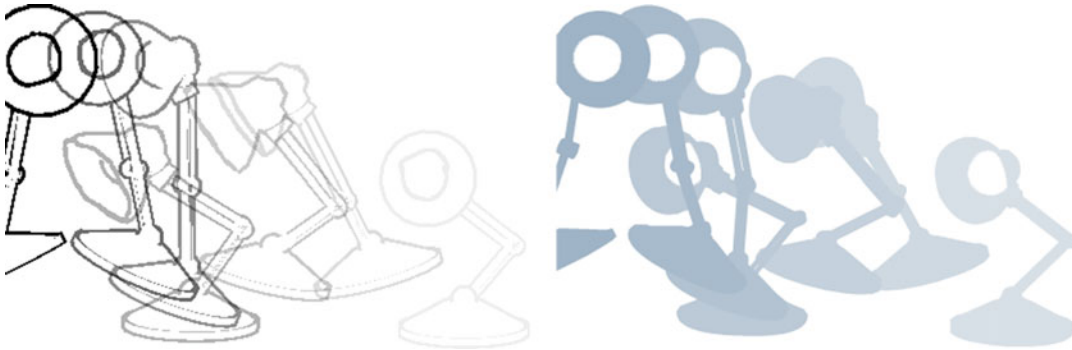
Jain et al. as well as other recent works (Xiao et al. 2015) propose pose descriptors that are translation and scale invariant. This is useful, as two characters with the same pose can have different sizes or be in different positions on the sketch. Descriptors that are not invariant to translation and scale can still be used, assuming that the characters in both the sketch and the 3D projection match (e.g., drawn storyboards that match the 3D scene).

To use various descriptors (e.g., edge maps and silhouettes like Gouvatsos et al.), it is good practice to normalize all values to be between 0 and 1. This way enforces values from different methods to be compared on the same scale.

For example, using joints to describe a pose can be effective, but using only a Euclidean distance to compare two poses is not invariant to translation or scale. To achieve an invariant pose descriptor $P_{\text{invariant}}$, Xiao et al. divide the joint



Sketch-Based Posing for 3D Animation, Fig. 9 Side-by-side comparison of drawings (*top*) and estimated 3D poses (*bottom*), for a horse model



Sketch-Based Posing for 3D Animation, Fig. 10 Side-by-side comparison of a sequence of drawings (*left*) and a sequence of estimated 3D poses (*right*), for a lamp model

distances P, by the overall height of the body H_{body}:

$$P_{\text{invariant}} = \frac{P}{H_{\text{body}}}$$

Jain et al. use a more complex but effective method as described in section "Database Approach for Automatic 3D Posing and Animation."

Supplying a Knowledge Base

The under-constrained nature of the problem can be resolved by viewing the same pose from different angles (Ivekovic et al. 2008). The interface by Guay et al. uses multiple views, as it is applied directly in a 3D environment. However, when only one sketch is available, a knowledge base is necessary to reduce the possible poses. Humans understand a drawn character's pose due to prior

knowledge, e.g., anatomically plausible poses or poses that make sense in context. Enforcing rotation limits on character's joints, assumptions about the type of character (e.g., humanoid), and databases are all suitable knowledge bases.

Restrictions on the 3D character's joints can be set by an artist with good intuition or by using real data (e.g., degrees of freedom of humans). However, for more stylized animation with exaggerations, the restrictions can be distracting for animators.

Making assumptions about the type of character can help reduce the number of possible poses greatly at the cost of reducing the problem cases a method can be applied to. For example, human-specific assumptions would mean that a method can only be applied on humanoid characters.

Databases come with similar trade-offs. For humanoids, mocap databases can be populated cheaply, using devices such as Microsoft Kinect. The data can consist of poses or whole 3D models (Kholgade et al. 2014). However, building comprehensive databases for noncooperative characters (e.g., elephants) is more complicated. Additionally, storing a large database and extracting information from it requires infrastructure and budget that smaller studios may not have.

Optimization Methods

Choosing an optimization method depends on how the problem is formulated. Jain et al. formulate the problem as a linear least squares system. Their algorithm is fast but only works with an orthographic projection. Gouvatsos et al. choose the particle swarm optimization algorithm, a global optimization method which makes no assumptions about the problem. Although the PSO scales well when parallelized on more powerful hardware, it is slower.

In all three cases, there is one common parameter: an *objective* or *energy* function. This function takes into account the chosen descriptors and transforms them into values that can be minimized. Guay et al. measure the difference in terms of positions and tangents of the bones. Jain et al. measure three terms: projection error, limb length error, and mocap regularization term. Gouvatsos et al. use a weighted combination of all pose descriptors:

$$f = w_1 D_j + w_2 D_s + w_3 D_e,$$

where D_j, D_s, and D_e are the differences in terms of joint distance, silhouette, and edge map, respectively. The weights w_1, w_2, and w_3 can be set to $\frac{1}{3}$ to have all descriptors contribute equally. Choosing and constructing this objective function is crucial and has to be done together with the design of the pose descriptors.

Sketch-Based Methods in Real Pipelines

Despite limitations in terms of possible poses and accuracy of results, production pipelines can still benefit from sketch-based methods. Final animation may still need the hand of an artist, but time and effort can be saved. Semiautomatic methods from Jain et al. and Gouvatsos et al. require little user input and allocate heavy work to the machine. Even if the accuracy of the results is not production ready, these methods can still serve as an automatic first pass for artists to build on.

The user input itself can take place during a cleanup pass of the drawings. Removing the user input completely would make these methods even more attractive, and future work can look into using medial axis methods to achieve this (Abeysinghe et al. 2008).

Moreover, combining all approaches together in one system could lead to a promising hybrid with most advantages and least disadvantages of all the methods.

Synonyms

S&R; *Skull*; *Skull and Roses*

Definition

The *Skull and Roses* (also known simply as *Skull*) is a multiplayer card game with small stochasticity, imperfect information, and partially observable outcomes. Consequently, like in the case of poker, it requires to mix bluffs, opponent modeling, and coalitions as high-level strategic plays, achieving all this with a very simple set of rules and elements.

Notation

There are four main parameters in *Skull and Roses* to be considered: the *number of players* P, the *initial number of skulls* $S = 1$, the *initial number of roses* $R = 3$, and the *number of wins* (successful challenges) required $W = 2$.

The original game has $3 \leq P \leq 6$, and the expansion – *Skull and Roses RED* – allows up to $3 \leq P \leq 12$.

History

It was created by Hervé Marly, illustrated by Rose Kipik, and edited by *Lui-même* in 2010. After that, the game gains its popularity very quickly, being officially published in German, French, and English. The game received the international price of as *d'or*, *jeu de l'année*, *Cannes 2011*.

This game is also known for the surprising fact that it took its designer, Hervé Marly, "15 years of perseverance" to properly balance it (Marly 2012).

Game Rules

A canonical game consists in a series of rounds composed by several turns; this decomposition is specified by the following rules (Marly 2012):

Game sequence:

1. Play a round.
2. If the last challenger is still playing, he takes the initiative.
3. If the last challenger is not playing, the next player, (*challenger* + 1) mod P, takes the initiative.
4. Repeat until winning condition is reached.

Round sequence:

1. *Do one First turn*.
2. Until a challenge is set, every player in clockwise order does either a *Card turn* or set a challenge, starting by the player that has the initiative.
3. Every player in order do either a *Bet turn* (aiming to become the challenger) or pass (definitively), until the challenger (player with the maximum final bet) is decided.
4. The challenger does a *Revelation turn*, until a skull is revealed or the number of roses revealed matches his own bet.
5. Let w_p be the number of games that challenger p has won so far. If the challenge is successful, increase w_p by one. Otherwise, do a *Discard turn*.

Turns:

- *First turn*: Each player places simultaneously a card in his own pile from his hand.
- *Card turn*: Place a card on the top of your pile from your hand.
- *Bet turn*: Increase the current bet.
- *Revelation turn*: If your own pile is not empty, turn up the top card of your own pile. Otherwise, turn up the top card of any player's pile.
- *Discard turn*: If the revealed skull is your card, choose a card to discard by yourself from your cards. Otherwise, let the owner of the revealed skull choose one of your cards to discard randomly. For both cases, the players other than you do not know which card was removed.

Conditions:

- *Starting condition*: Each player has three roses and one skull and zero win. And Player 1 takes the initiative.
- *Winning condition*: Either winning two challenges or being the last player standing.
- *Successful challenge*: The challenge is successful, if the challenger revealed a number of roses equal to the bet without revealing a skull.

Skull and Roses Card Game, Table 1 The upper bound of state-space size for all possible player values in *Skull and Roses RED*

#Players	3	4	5	6	7	8	9	10	11	12
Upper bound	10^{13}	10^{16}	10^{20}	10^{24}	10^{27}	10^{31}	10^{34}	10^{38}	10^{42}	10^{45}

- *Unsuccessful challenge*: The challenge is unsuccessful, if the challenger revealed a skull in the process of the challenge.

Game Complexity

In order to measure the complexity of a game, there are two well-known complementary approaches: the computational complexity one, given by the complexity class; and the combinatorial game theory one, given by the state-space, game tree, average game length, and average branching factor.

Complexity Class

Skull and Roses is a polynomially bounded game, where resources (hand cards) are used up, and is also a game of imperfect information (each player's hand and pile status).

According to standard book in the field by Hearn and Demaine 2009, the natural extension (parametrization of the number of players, wins, skulls, and roses) of games with these two key characteristics, the two-player version of the game is in *PSPACE*, while the *N*-player version is in *NEXPTIME*. There are proofs to show that many games with those characteristics are in *PSPACE – complete* and *NEXPTIME – complete*, respectively, but the proofs for *Skull and Roses* remain unknown.

State-Space Complexity

The state-space complexity deals with the total number nodes in the game's state graph; this is given by the number of variables needed to fully represent a game-state and their domain sizes.

The upper bound below for the natural extension of the game was proven in Gragera et al. (2013) by bounding the variables in each individual turn (Table 1):

Game-Tree Complexity

$$Size(\text{State} - \text{space}) \leq P^2(R+S)^2 \cdot \left[R + 2 + (R+1)^{P-1}\right] \times \left[4(S+1)^2(R+1)(W+1)\binom{S+R}{S}\right]^P$$

.

The game-tree complexity considers the size of the game tree, a directed graph whose nodes are positions in a game and whose edges are the moves that were played between them. The size of this tree is measured by the number of leaf nodes in the game tree rooted at the game's initial position. This value is equivalent to the total number of possible different games that can be actually played.

An upper bound for the tree size of a single round was given in Gragera et al. 2013 (Table 2):

$$Size(\text{Round tree}) \leq \#placements \cdot \#bets \cdot \#revelations.$$

And a very naive and loose upper bound was also obtained for the full game tree simply by using this bound (with the first-round values) for all possible rounds (without considering the Discard turn):

.

$$Size(\text{Game tree}) \leq (\#Placements \cdot \#Bets \cdot \#Revelations)^{\#Rounds}$$

Skull and Roses Card Game, Table 2 The upper bound of a single round tree size for all possible player values in *Skull and Roses RED*

#Players	3	4	5	6	7	8	9	10	11	12
Upper bound	10^{10}	10^{17}	10^{25}	10^{33}	10^{41}	10^{50}	10^{60}	10^{70}	10^{80}	10^{90}

Skull and Roses Card Game, Table 3 The average length of a game and the average branching factor for all possible player values in *Skull and Roses RED*

#Players	3 players	4 players	5 players	6 players	7 players
Avg. game length	58	130	244	409	633
Avg. branching factor	5.262	9.175	14.445	21.868	32.897
#Players	8 players	9 players	10 players	11 players	12 players
Avg. game length	922	1,282	1,720	2,242	2,856
Avg. branching factor	50.119	78.320	126.218	209.773	358.761

Average Game Length and Branching Factor

The game length is the number of position of each game, the depth of the tree, while the branching factor is the number of children at each node, the outdegree. Both higher branching factors and higher game lengths make search algorithms computationally more expensive and ineffective, due to the exponentially increasing number of nodes and the so-called horizon effect (Table 3).

The previous averages were calculated based on the data collected by 10^7 games played by uniform random players (Gragera et al. 2013).

Future Directions

These conditions make it very attractive as a test-bed for game AIs in the big picture versus quick profit dilemma as well as a good candidate to be included in general game playing test frameworks and competitions (Genesereth et al. 2005).

Due the novelty of the game, still several important problems remain open, being the two most important to find a not naive game tree upper bound and to prove its exact complexity classes.

Calibration thermal imaging; Physiological monitoring

Definition

The accurate and robust ROI detection and tracking in thermal faces can lead to better physiological monitoring. The calibration between RGB-D and thermal cameras allows fee body movements in practice, helping to achieve such goals. This article presents two smart schemes to make the chessboard pattern with black and white squares visible to both cameras during the calibration process.

Introduction

The thermal infrared sensor (Gade and Moeslund 2014) is capable of recording small facial temperature variations because of its high sensitivity to thermal radiations emitted from the skin. Compared with traditional contact and wearable devices (Park et al. 2008; Storck et al. 1996), the thermal imaging process can be carried out in a contactless and unobtrusive way without discomfort. More importantly, the collected thermal data can be used to measure the physiological parameters such as the body temperature, respiration rate, and heartbeat rate. Thus, thermal imaging makes continuous health monitoring of human beings convenient and comfortable but not noticeable, especially benefiting the neonatal infants, children, and elderly people.

Many approaches have been proposed for the physiological monitoring based on thermal imaging (Al-Khalidi et al. 2011; Chauvin et al. 2016; Chekmenev et al. 2007; Fei and Pavlidis 2010; Garbey et al. 2007; Murthy and Pavlidis 2006). The first key step is to identify the regions of interest (ROIs) like forehead, nose, mouth, cheeks, ears, and neck from the detected face, and track them in each frame image appropriately. Usually, the mean thermal signal of the nostril region carries the breathing information, and the average temperature change along the superficial blood vessel in the neck area reveals the heartbeat information. The accurate and robust segmentation of these ROIs is crucial to the overall performance. The main challenge comes from the head movements of the subjects. In most previous works (Alkali et al. 2013; Chauvin et al. 2016; Chekmenev et al. 2006, 2007; Fei and Pavlidis 2010; Murthy and Pavlidis 2006; Sun et al. 2005; Yang et al. 2008), the subjects were instructed to stay still during the course. However, they usually exhibit small head motions. More practically, large movements can often be found.

To overcome the inaccuracy caused by small movements of the subjects, Fei et al. (2005) applied a tracker based on iterative image registration (Lucas and Kanade 1981) to the nasal tip area. Aiming at automatically following the breathing signal, a robust and stable Bayesian tracker utilizing the mean shift localization (MSL)-based (Fukunaga and Hostetler 1975) particle filtering was proposed in (Zhu et al. 2005). This tracker can cope with significant head movements, but it fails in the scenario that more than one window of the tracking ROI is lost or blocked during the process. In addition, the particle filtering is computationally expensive. In (Fei and Pavlidis 2010; Murthy et al. 2009), the authors adopted the coalitional tracking algorithm (Dowdall et al. 2007) to deal with the subject's motion during the breathing measurement. It employs a cluster of collaborative particle filter trackers and optimizes the multitracker interaction through game theory to gain both accuracy and robustness. It is worth noting that the behavior of the coalitional tracker is not absolutely deterministic due to the stochastic components of the particle filter trackers. The nostril ROI is then extracted by conducting integral projections on the edge image obtained from the original thermal face image applying a 3×3 Sobel edge detector. The leftmost and rightmost maxima of the vertical integral projection generate the respective left and right outer edges of the nostril, and the peak of the horizontal integral projection produces the nostril's base edge.

To actively track the mouth-nose region, Chauvin et al. (2016) modified the tracking, learning, and detection (TLD) predator approach (Kalal et al. 2010) to make it adaptive to the thermal data. With a manually initialized ROI, the TLD algorithm produces the coordinates and

size of the bounding box for each frame using a minimum set of features. If the tracker module loses the ROI, the detector module will reinitialize the tracker with a new bounding box obtained by an exhaustive search using a sliding window method. Therefore, this technique can handle relatively large head movements. Similarly, they implemented the 3 × 3 Sobel operator to extract the contours of the mouth-nose ROI and then yielded the mask by setting all the pixels with a gradient value less than the specified threshold to zero. The ROI is attained by employing the mask operation on the contour image.

Yang et al. (2008) manually initialized a region for the first frame, which is then divided into a series of nested regions (R^i) based on an incremental temperature step (ΔT) and a reference temperature (T_{ref}) which is the mean temperature of all the pixels on the bounding box of the initialization region. By selecting the optimal threshold ($T^* = T_{ref} + i^*\Delta T$) that makes the area of region R^i* drop sharply against the area of region R^i*-1, the ROI of the first frame is chosen as the region with largest connected component in R^i*. Correspondingly, the ROIs of the subsequent frames are attained by employing the same T* to compute the isotherm and tracking the contour utilizing energy minimization.

In practice, traditional thresholding (e.g., Otsu's adaptive thresholding [Alkali et al. 2013, Lampo et al. 2009, Murthy and Pavlidis 2006]) and edge detection (e.g., Prewitt operator [Al-Khalidi et al. 2010, 2011, 2015]) are also widely used for the ROI segmentation. In some investigations (Alkali et al. 2014; Garbey et al. 2007; Sun et al. 2005), the ROIs are even manually placed to ensure the high accuracy of segmentation, which is time consuming and susceptible to subjective errors.

Ideally, the person under estimation should be able to move around without constraints. To cope well with such free head movements, this article introduces the calibrate method integrating the thermal sensor with the RGB-D sensor to produce more reliable ROI segmentation results, taking advantage of the RGB-D imaging in face detection and landmark points extraction.

Approaches

Most of previous approaches for measuring the physiological data generally work under certain environments such as temperature-controlled room, subjects sitting comfortably in a chair (remaining still or with small movements), facing to the camera, and within a specific distance from the camera. Sudden temperature changes and body movements are the main challenges to the physiological monitoring. Although researchers investigated different methods (Al-Khalidi et al. 2011; Alkali et al. 2013, 2014; Chauvin et al. 2016; Fei and Pavlidis 2010; Garbey et al. 2007; Murthy et al. 2009; Murthy and Pavlidis 2006; Sun et al. 2005; Yang et al. 2008) to alleviate small head motions of the subjects, large or free head movements in real applications are still a major factor affecting the overall accuracy. The direct segmentation of the thermal images using thresholding and face landmark points detection applying the Dlib algorithms (King 2009) usually produces results with noises. To accurately evaluate the facial temperature evolution of the subjects, a RGB-D camera can be potentially utilized to guide the localization of the ROIs in the thermal data. This necessitates a stereo calibration between the thermal and RGB-D sensors using a chessboard pattern with black and white squares.

As illustrated in Fig. 1, the thermal and RGB-D sensors are mounted on top of a robot at 1.3 m and 1.1 m from the floor, respectively. The comfortable distance between the robot and the subject is about 1.0 m. The chessboard can be easily detected by the RGB camera; however, the black and white squares cannot be differentiated by the thermal camera as their heat radiations are more or less the same. To make the chessboard pattern visible to both sensors during the calibration process, Zhao et al. (2018) designed two smart schemes.

Calibration Using Combined Chessboard

The 8 x 6 chessboard pattern with 23.5 mm black and white squares is used for the calibration, where all the black squares in a thick white cardboard of A4 paper size are first removed, and then

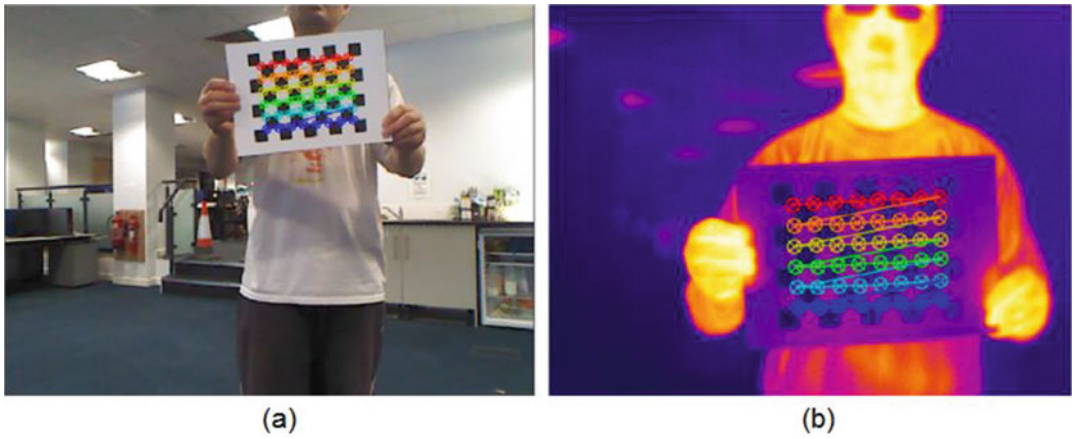
Smart Calibration Between RGB-D and Thermal Cameras for ROI Detection and Tracking in Physiological Monitoring, Fig. 1 RGB-D and thermal sensors mounted on top of a robot

heated using a 300 W incandescent lamp for several minutes (see Fig. 2). At the same time, a thin black sheet of the same size is cooled down in a fridge for a few minutes to bring it to a low temperature. The two sheets are then combined together so that both cameras can see this black and white chessboard pattern, as the white cardboard and black sheet appear as white and warm, and black and cold in the RGB-D camera and thermal camera, respectively (see Fig. 3).

Calibration Using Electrically Heated Chessboard

The combined chessboard is visible to the thermal camera for at most 5 minutes as the temperature difference between the white cardboard and black sheet diminishes, and the operation procedure is not very convenient. Sometimes, the heating and cooling processes need to be carried out twice for one calibration. Each time before calibration, it also takes some time to finish the heating and cooling. To overcome these shortcomings, an electrically heated chessboard was designed (Zhao et al. 2018), which consists of a 3 mm black acrylic sheet at the back and a 1.5 mm bicolor (black on

Smart Calibration Between RGB-D and Thermal Cameras for ROI Detection and Tracking in Physiological Monitoring, Fig. 2 Lamp for heating the white cardboard



Smart Calibration Between RGB-D and Thermal Cameras for ROI Detection and Tracking in Physiological Monitoring, Fig. 3 Calibration of the RGB-D camera and thermal sensor using a combined chessboard. (**a**) Detected pattern in RGB image and (**b**) detected pattern in thermal image

white) laminate sheet at the front. The chessboard pattern is manufactured by precisely carving the black squares using a laser cutter. Each corner of the white and black squares is then associated with a resistor. When the power is on, the resistors emit radiations, which can be detected by the thermal camera, as depicted in Fig. 4.

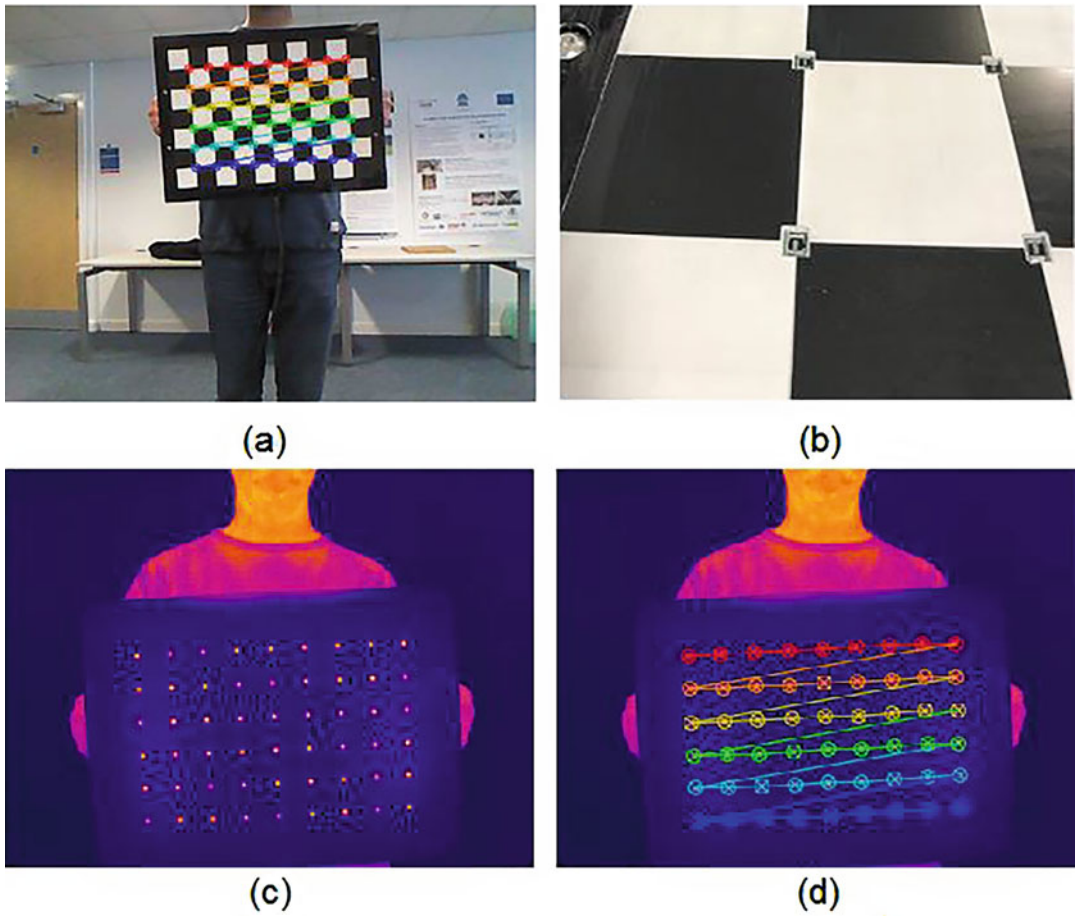
In comparison with the combined chessboard, the calibration procedure by this pattern can be conducted immediately after turning on the power. Moreover, the resistors can be heated for a much longer time, enabling to perform multiple calibrations continuously. It is worthy to note that the resistors may be overheated after too long time (e.g., more than 30 minutes), which could affect the calibration results.

Performance Evaluations

As demonstrated in Fig. 1, the RGB-D camera used in the experiments is Microsoft Kinect V1 (2018) with an 8-bit RGB resolution of 640 × 480 pixels and an 11-bit monochrome depth of the same resolution. Its frame rate is 9–30 Hz. The higher the resolution, the lower the frame rate. In addition, the sensor has a practical distance ranging from 1.2 m to 3.5 m, and an angular field of view (FOV) of 57° (horizontal) and 43° (vertical). Meanwhile, the employed thermal sensor is Optris PI 450 (2018), which has a high sensitivity to temperature (0.04 °C) and an image resolution of 382 × 288 pixels. Its frame rate ranges from 27–80 Hz. The sensor lens has a relatively narrow FOV and a fixed focus length (38° horizontally and 29° vertically with 15 mm lens).

It takes about 3–5 minutes to complete the calibration process, where 80 or 150 sets of 48 corner points are recorded. Based on the pinhole camera model, the intrinsic parameters of both cameras together with the rotational and translational transformation between cameras are estimated via stereo calibration. Face detection and landmark points extraction in the RGB images are obtained by utilizing the Dlib machine learning toolkit (King 2009) based on the histogram of oriented gradient (HOG) features (Dalal and Triggs 2005). Since the target person is assumed not to move significantly between two consecutive frames, the face detection task is performed in a local window corresponding to the face previously detected, thus speeding up the detection process. If this cannot be done, the face detection is carried out completely in the new frame image.

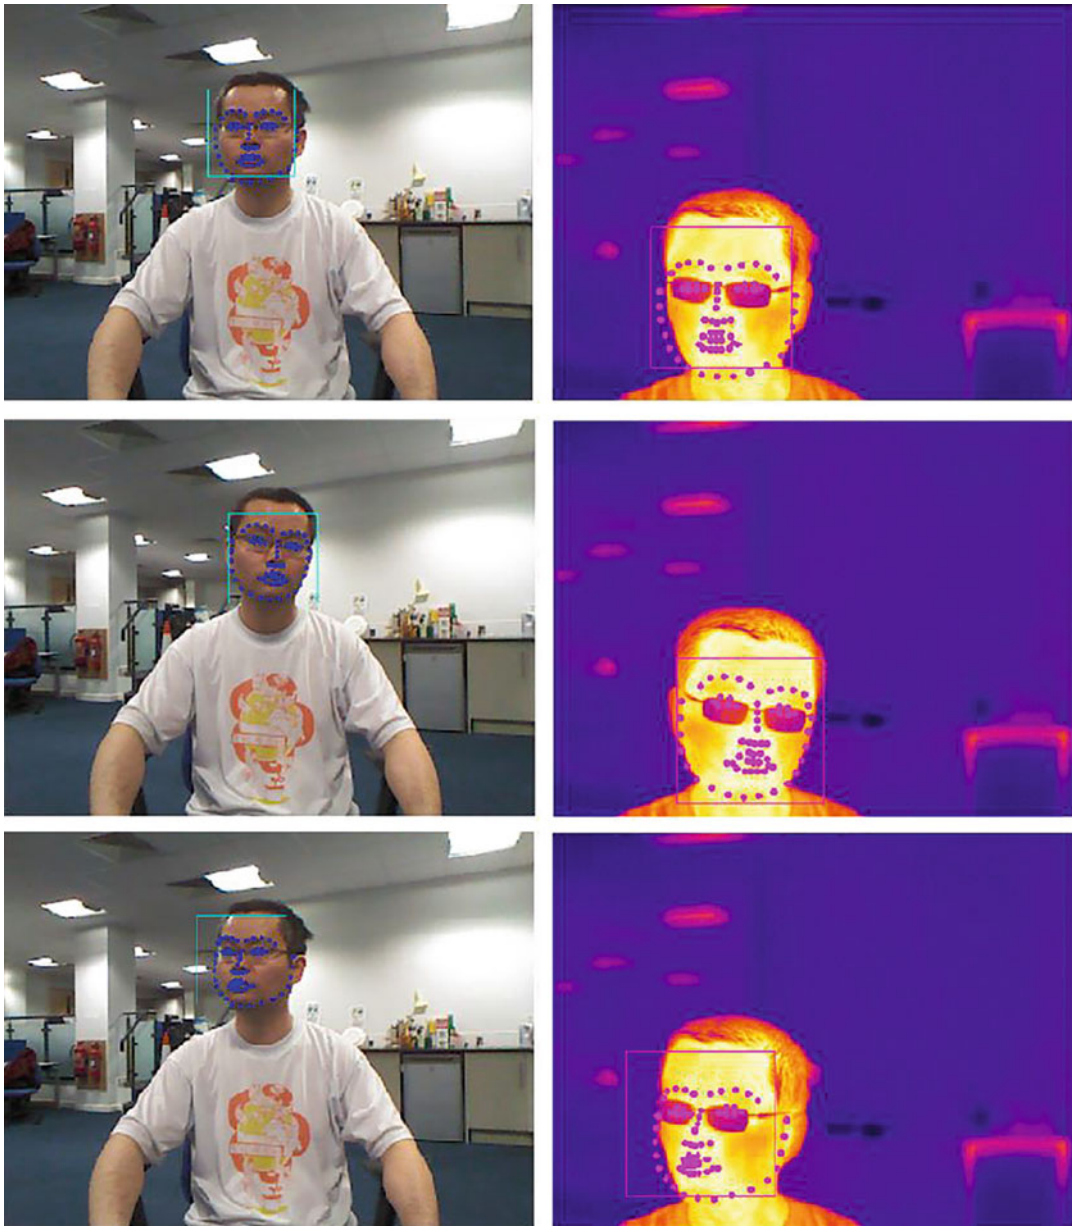
As a consequence of the calibration process, the translation vector and rotation matrix are utilized to map the detected face and landmark points in the RGB image to the corresponding thermal



Smart Calibration Between RGB-D and Thermal Cameras for ROI Detection and Tracking in Physiological Monitoring, Fig. 4 Calibration of the thermal camera with the RGB-D sensor using an electrically heated chessboard. (**a**) Detected pattern in RGB image, (**b**) resistors for heating the chessboard, (**c**) thermal image of the heated chessboard, and (**d**) detected pattern in thermal image

image (see Fig. 5). It can be seen that the person can move around freely and the calibration results are very encouraging. The robust detection results in the thermal data lead to accurate ROIs, which will produce much better physiological measurements.

As described in Fig. 6, the facial ROIs (forehead, nose, and cheeks) in the thermal image can be properly located with respect to the calibrated landmark points. For instance, the forehead center can be considered as the middle of the two eyebrow corner points. Accordingly, the average temperature in the forehead area is computed as the body temperature. The evolutions of the mean temperature in the nose and cheek areas along the timeline are used for the measurement of the respective respiration and heartbeat rates applying harmonic analysis. Figure 7 displays an example of the physiological monitoring results by fast Fourier transform (FFT) (Chauvin et al. 2016; Garbey et al. 2007), where the dominant frequency with the highest peak magnitude in the temperature signal's spectrum is identified, and then multiplied by 60 to obtain the respiration or heartbeat rate in cycles per minute. Compared with the ground truth data obtained by a contact thermometer and a wearable oximeter, the calculated body temperature error is within 1 °C, and the estimated respiration rate of 15 breaths per minute



Smart Calibration Between RGB-D and Thermal Cameras for ROI Detection and Tracking in Physiological Monitoring, Fig. 5 Calibration results overlaying on the RGB and thermal images in three orientations

(BPM) is accurate, while the measured heartbeat rate of 95 beats per minute (BPM) needs to be further improved. It was explained that the relatively big bias of the heartbeat is because of its larger variation range than that of the respiration, and it can be reduced by denoising the input temperature signal (Zhao et al. 2018).

Discussion

During the calibration, two conditions need to be satisfied: i) both cameras detect a complete chessboard and ii) all the corner points on the chessboard can be identified by both cameras. In presence of more than one subjects, the calibration

procedure can still be done, as demonstrated in Fig. 8. Furthermore, the calibration approach can address the issue of prohibiting subjects from wearing glasses mentioned in many existing methods (Al-Khalidi et al. 2010, 2011, 2015; Zhu et al. 2005). Nevertheless, it was noticed that the calibration can only be successful when the chessboard is placed within an effective

S

distance range of 60–90 cm because of the different FOVs of the two cameras, especially the limited FOV of the thermal sensor. This means that many adjustments have to be conducted to match the FOV of the thermal camera with the other RGB camera (Kinect V1 in this article). In practice, having a motorized pan-tilt unit (PTU) to mount the two cameras could help with this difficulty.

Another reason is that the lens of the thermal camera has a fixed focus length, which means that the acquired image is very clear at a specific distance range, but becomes a bit blurring outside of this range. For average temperature measurement within a ROI, it is not really a problem since it already acts as a low-pass filter, but this could be an issue for extracting a very small feature (e.g., chessboard corner points) on a wide range of distance. Since high-cost thermal cameras with lens of adaptive focus lengths are available on the market, this problem can be alleviated.

To speed up the calibration, a chessboard with bigger square size (e.g., 6 × 3 with 35.0 mm squares) can be implemented. Particularly, it is

Smart Calibration Between RGB-D and Thermal Cameras for ROI Detection and Tracking in Physiological Monitoring, Fig. 9 Deviations of the mapping face landmark points on the thermal images when the subject moves (**a**) backward and (**b**) forward

more convenient and faster to complete the calibration procedure using the combined chessboard. Moreover, the range of the effective distance between the chessboard and the sensors is enlarged to 70–150 cm. Additionally, the frame rates of the RGB and thermal cameras may not coincide with each other. However, this will not greatly influence the ROIs detection and tracking, as the subjects usually keep still within a very short period of time. Thus, the same calibration results are valid for a few consecutive frames. In real applications, this can also be used to accelerate the calibration process.

Due to the narrow FOV and fixed focus length of the thermal sensor, the effective distance between the subjects and the cameras for physiological monitoring after calibration is within a limited range as well. For the 8 × 6 chessboard, it is about 1.0 m. In case that the 6 × 3 chessboard is used for calibration, this distance becomes 1.0–1.1 m. For both cases, the subject's moving forward or backward from the sensors will make the calibration results on the thermal data shifted (see Fig. 9). This problem can be solved by keeping the distance between the subject and the cameras through robot navigation, or employing a costly thermal sensor with multiple lens.

Conclusion

With the advent of portable and affordable thermal cameras of high performance (e.g., FLIR ONE 2018; Seek CompactPRO 2018) that can be easily attached to smartphones, thermal imaging is becoming more and more popular and it

plays an important role in contactless physiological monitoring. Taking advantage of both the RGB-D and thermal imaging, the calibration approaches can tackle large or even free head movements occurring in thermal-based measurements of physiological parameters. It was reported that the calibration of thermal sensor with RGB camera is feasible and the two calibration strategies introduced in this article can benefit the ROIs segmentation and tracking, thus leading to more promising estimation results. To further improve the calibration accuracy and finally produce better physiological monitoring results, it is worthy to apply the circle-pattern chessboard instead of traditional square-pattern chessboard.

Smart Connected Toys

Definition

A smart toy is defined as a learning or play device consisting of a physical toy embodiment with electronic components that connects to a computing system with online services through networking and sensory technologies to enhance the functionality of a traditional toy.

The Concept, Phenomena, and Key Principle

A smart toy is defined as a learning or play device consisting of a physical toy embodiment with electronic components that connects to a computing system with online services through networking and sensory technologies to enhance the functionality of a traditional toy. It is an entity built to talk, learn, remember, and respond to a child's request. A smart toy in this context can be effectively considered a computing device or peripheral called smart toys. Smart toys carry both novel and industrial challenges with technical and sociotechnical issues as well as compelling computing technologies in Cloud-connected smart toys. The smart toy is a new cross-discipline research topic in computer science, information systems, and social sciences. Some examples of smart toys include Mattel's Hello Barbie, CogniToys' Talking Dino, and Fisher-Price's Smart Toy Bear. United Kingdom-based Juniper Research has reported that smart toys and related applications are the new key market for toy companies and the sales of smart toys would grow from $2.8 billion in 2015 to $11.3 billion by 2020.

Historical Parts: Landscape

A toy is an item or product intended for learning or play, which can have various benefits. Toys have been part of every culture, as a uniquely designed product for learning, socialization, leisure, and play and intended to benefit children as they go through various developmental stages. Children use toys to discover their identity, learn causes and effects, explore relationships, and practice skills. Children's toys have become increasingly sophisticated over the years, with a

growing shift from simple physical products to toys that engage the digital world as the Internet of Things (IoT). Toy makers are seizing this opportunity to develop products that combine the characteristics of traditional toys such as dolls and stuffed toys with computing software and hardware called Smart Toys. Toy makers have embraced modern technologies such as mobile technology into the design of their products, reshaping the concept of toys (Hung 2015)

Results, Procedures, Processes, Methodology, and Historical Parts

Toy makers such as Hasbro and Mattel have released toys that integrate with networking and sensory capabilities to allow them to detect and interact with their environment. A smart toy works through some form of connectivity (either Bluetooth or WiFi) and can download software and conduct activity through WiFi to a connected source in the Cloud (Tang and Hung 2017). This introduces a service-oriented architecture (SOA) approach between the toys (service providers) and children (service requestors). In general, there are three properties of a smart toy: (1) pervasive, a smart toy may follow the child through everyday activities; (2) social, social aspects and multi-player are becoming a mandatory aspect of interactive smart toys in a one-to-one, one-to-many, and many-to-many relations (Tath 2006); and (3) connected, smart toys may connect and communicate with other toys and services through networks. For example, CogniToys' Dino can listen and answer questions raised by children by voice because the Dino connected to the IBM Watson's Knowledge called Elemental Path's "Friendgine," which a kid-friendly database at the backend is. The integration of smart toy with functionalities, which allows collection, storage, transmission and processing of play information, and generated context data is essential and providing the required interactivity of the smart toy. Smart toys are evolving with continuous feature sets and integrating new technology, which allows players to be more interactive, and individualized with personal preferences. In smart toys, the fusion of data from cameras and sensors allow for a more comprehensive and non-obtrusive observation of people for user behavior analysis (Salah et al. 2013). This context data model will adopt the definition from the World Economic Forum (2011) as follows:

1. Volunteered Data: data that is explicitly provided by the children. This can include personal profile information or preference settings, e.g., the child name and date of birth.
2. Observed Data: data not directly given by the children but is detected by the smart toys often through a sensor, e.g., GPS location and time.
3. Inferred Data: data deduced based on analysis of a combination of volunteered and/or observed data. A lot can be evaluated about a child and their environment through inferences based on context data by third party influencing, e.g., integrate with the information from social networking sites and Google Map.

VR Sociable Network

Definition

Social Virtual Reality is a web-based social interaction paradigm, mediated by immersive technologies and taking place in predesigned three-dimensional virtual worlds where individuals, represented by an avatar, may engage in real-time interpersonal conversation and shared activities.

Introduction

Immersive Virtual Reality (VR) evolves for over five decades, whereas the vision of cognitive transcendence to *another reality* could date as far back as the eighteenth century (Grau 2003). The

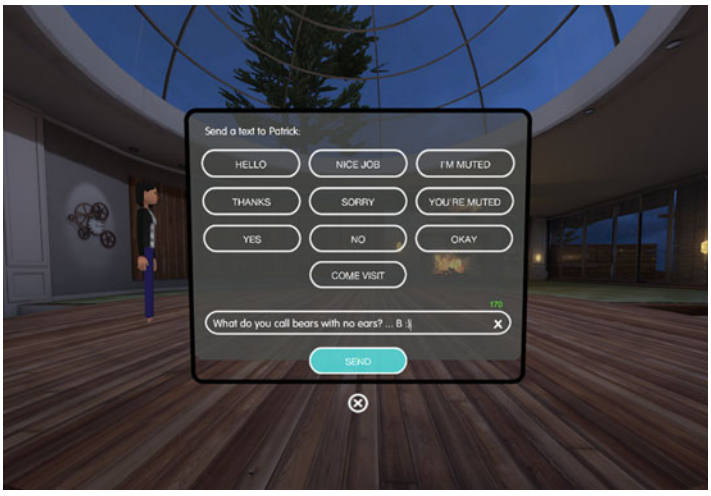
simplest explanation for the much delayed commercial breach of Head Mounted Displays (HMDs) is that the level of immersion is a direct effect of applied illusory techniques (Slater and Wilbur 1997). Therefore, even though original HMD prototypes were developed by Ivan Sutherland in the mid-sixties (Sutherland 1968), being dependent to the autonomous development of contributing technologies – and those are multiple – VR-related progress was slow, but most importantly un-marketable.

Advancements in the overall quality of displays, in combination with the diffusion of Smartphones, enabled the commercial release of affordable VR headsets such as the Google Cardboard and Samsung Gear VR, while HMDs like Oculus Rift and HTC Vive came with built-in displays offering superior content-projection quality. The commercial success was followed by the industry's tapping of an established market, social networks. Thus, social VR refers to the combination of (a) web-based social networking and (b) an egocentric flow of information, a distinctive trait of both immersive VR and users' profile structure in social media. It could be regarded as the *second generation of social networking*, incorporating immersive technologies, which allow users to engage in synchronous, interpersonal interaction with friends or strangers, in predesigned, web-based, three-dimensional (3D) virtual environments (VEs).

Emergence of Social VR

One of the first known attempts in immersive social networking was that of AltSpace (https://altvr.com/), a software company which began developing its homonymous platform in 2013, approximately 2 years before the wide-spread release of HMDs and launched it in May 2015. AltSpace, which has also been the first to embrace the term "social VR," announced closing down due to lack of investors, until its acquisition by Microsoft in October 2017. Starship, a VR/AR (augmented reality) innovation company, launched vTime (https://vtime.net/) in December 2015. Finally, in April 2017, Facebook introduced Facebook Spaces (https://www.facebook.com/spaces) and essentially solidified social VR, since, unlike other platforms, it is structured upon users' existing accounts, uploaded media, and network of friends. Other social VR platforms include Oculus Rooms, VRChat, and Sansar, developed by Linden Lab, the company best known as the creator of Second Life.

Basic functionalities of Social VR platforms entail use of immersive technologies such as HMDs and data-gloves, avatars, and virtual worlds where users can interact among each other in a variety of ways; for instance, AltSpace allows private messaging (see Fig. 1). In addition, some platforms allow users to participate in shared activities like playing games and attending social events. There are also features that could be



Social Virtual Reality, Fig. 1 Private messaging option. (Image courtesy of AltSpaceVR)

Social Virtual Reality, Fig. 2 vTime's *Personal Shield* function. (Image courtesy of vTime)

regarded as a form of Mixed Reality, such as projections of videos, websites, or other media onto virtual screens, visible to all users present. Finally, they feature cross-platform usage and support live videocalls and communication via any application (email, SMS, Facebook Messenger, Skype, etc.) that allows content sharing.

Social VR and Communication

The potential of VR as a communication medium has been foretold over two decades ago (Biocca and Levy 2013) and by all accounts, Social VR is synchronous interpersonal communication. However, it is differentiated from computer-mediated interaction with respect to several aspects.

First, typical social networking is computer-mediated (CMC), text- or image-based, offering both synchronous (by featuring chat and secondary functionalities of video and audio calls) and asynchronous forms of communication. Social VR, although certainly still computer-mediated, would be better described as a simulation of face-to-face (FtF) communication; apart from the use of anthropomorphic 3D models (as the *embodiment* of one's social profile – avatar), the ability for synchronous dialogue (via audio intercommunication), real-time head-tracking, spatialized audio and the incorporation of some germinal nonverbal cues (such as -basic- body posture, e.g., sitting/standing, facing/or not interlocutors, some hand gestures etc.), and proximity between communicators vastly alters the experience of social networking (see Argyle 1988). For instance, both AltSpace and vTime allow the activation of a shield (see Fig. 2), preventing users from virtually touching shielded avatars or invade their personal space.

To this list, we could also add a sense of *being watched*, which is never the case in computer-mediated social networking. Finally, VEs provide an additional aspect to the interaction, since sceneries convey information of *social context* (see Dzardanova et al. 2018) with the probability of affectively impacting communicators' social behavior (see Goffman 1959).

Conclusion

Social VR platforms have not been extensively studied and lack of full body-motion control, haptic feedback, and incorporation of the full spectrum of nonverbal cues possibly affects the overall fidelity. Comparative research and laboratory-based social experiments are in need. Furthermore, VR is a set of continuously evolving technologies, and even though their growth rate is expected to rise significantly in the next few years, it is still unclear whether social VR will hold as a standardized means of social networking.

Definition

Online games are games that are hosted on a server or that can be accessed by multiple people from different locations. *Social games* rely on the interaction with other (human) players or have strongly interaction-tailored elements. *Multi-player games* are games designed to be played by multiple players at the same time, be it collaboratively or in competition with each other. *Mobile games,* i.e., games that can be played on mobile devices, intersect with all of these three game types.

Introduction

One game, more than any other, has defined a generation in the sense that one is hard pressed to find someone who has *not* played it. That game is *Pac-Man*, invented by Toru Iwatani for Namco Limited in, 1977 (Lammers 2006). The game holds the (Guinness) world record as the *most successful coin operated game ever* (Limited 2008) and is considered by experts such as Levy (2010) to be *the* most famous computer games of all times. For completeness, it should be noted that the 1978 arcade game *Space Invaders* (by Tomohiro Nishikado) is ranked by historical reviews such as Glenday (2009) as the *top arcade game ever*; its arcade version famously causing coin shortages in some countries. *Pac-Man* was created in the earlier years of computer games but it has not lost in appeal at all; for a brief few days it recently resurfaced and shook the world of online gaming: when Google displayed a fully playable version of the game as its logo (maintained for public use at http://www.google.com/pacman/) in May 2010 and made it freely available to anyone on the internet, the world once again played the game excessively. As a result, and over the course of only 3 days, the reported loss in man-hours and productivity across the globe is estimated to greatly exceed $100 million.

These damages seem huge; however, Kushner (2011) already estimated the worldwide gaming community to have grown from 200 million in

2001 to 1 billion by 2011. In 2007 the Entertainment Software Association stated that *"US computer and video game software sales grew six percent in 2006 to $7.4 billion – almost tripling industry software sales since 1996".* By 2008, Bohannon (2008) estimated gaming to be $11 billion industry. These are relatively old numbers, but they plot a decade-long trend. This trend continues until today and does so with staggering numbers: according to Ojala and Tyrvainen (2011), over the last decade the entire software industry (i.e., not just games) has taken the shape of a $200 billion software division and a $500 billion service industry. According to Anderton (2017), the economic impact of the gaming industry (where computer games have long since replaced traditional board and card games in overall profit) to the US GDP in 2016 was $11 billion, with the global industry exceeding $90 billion.

Mobile Devices and their Impact on Computer Games

Two technology driven trends have recently taken the concept of games, and game-play, from being isolated activities and blown them across all spectra of everyday lives of ordinary people: social networks and mobile devices.

Handheld Consoles and Smart Phones as Gaming Devices

Mobile gaming on programmable devices was introduced quite early in the history of gaming, with devices like the *Microvision* (Wolf 2008) or Nintendo's *Game & Watch* (Gorges et al. 2012) being released in 1979 and 1980, respectively. However, the world was not yet ready for *Microvision* and it was produced only until 1981 (Firestone 2006). *Game & Watch* did much better: until it was discontinued in 1991, more than 43 million units were sold and in its 11 years, 60 games were produced for it (Stanton 2015).

The big-break through was clearly the Nintendo *Game Boy* (1989) (Tobin 2013), considered by an entire generation to be *the* handheld unit (Herman 1994). In various incarnations, it sold close to 120 million units in its life time. The *Game Boy* was a major factor for the success of one of the most successful games in history: *Tetris* (Ackerman 2016; Brown 2016). Seeing the success of the *Game Boy,* Sega produced the *Game Gear* (1990) but not nearly with the success of the *Game Boy.* At the end of its life cycle, the *Game Gear* only sold around 11 million units. Nintendo could also follow up to the *Game Boy* with the *Game Boy Advanced* (2001) selling over 80 million units in its considerable shorter life time compared to the *Game Boy* variants. In 2004, as Nintendo released a new handheld console called the *Nintendo DS,* a new competition entered the market of mobile gaming: Sony released their *PlayStation Portable (PSP)*. While the *PSP* was a success selling over 80 million units, its successor the *PlayStation Vita* (2011) failed to deliver: after selling only 15 million units no further follow up device/product was created. With Sony dropping out, Nintendo seems to be the only company being able to succeed in the handheld market, and indeed, the company created commercially successful handhelds in every console generation since the *Game Boy.* Notably, *while the Wii is very often crowned as the winner of the* seventh console generation, continuously selling almost as much as the *XBox360* and *PlayStation 3* combined, the *Nintendo DS* and *3DS* almost sold 50% more than the *Wii*.

The Commercial Success of Mobile Games

In 2005, Chehimi et al. (2005) predicts that *"mobile games will be one of the most commercially successful applications on mobile phones."* They were considered to be a *killer application* and individually attract millions of subscribers worldwide (Aiolli and Palazzi 2009). The revenues they generate are reported to be *"in the order of billions of US dollars worldwide"* (Yan 2003). They are considered to be among the most proliferating industries (Wong et al. 2010) and experience growing demands, with an estimated 40% growth each year: according to Palazzi and Maggiorini (2011), games also represent one of the most successful applications for smart phones.

Even though mobile gaming on smart phones or PDAs was already possible in the early 2000s (Inam et al. 2017) with *Windows Mobile* devices

or devices like the Nokia *NGage,* the success of the iPhone (2007) and the following success of Android (2008) opened a complete new market for mobile gaming. That mobile market is estimated to have grown to $24.5 billion by the end of 2014 (Wang and Che 2016). The most downloaded paid and unpaid apps list are continuously filled with – and often lead by – games. For instance *Candy Crush* has more than 20 million downloads on the Google Playstore alone which can easily compete with AAA games on the consoles such as *Call of Duty.* While fully paid games exist they are a minority on the app stores. Smart phone games quite often rely on the *free2play* model (Soroush et al. 2014), providing a free base game and requiring minor transactions for in-game items. Because of this, *free2play* games are often developed in ways which encourage the user to buy additional in game items.

The continuously increasing processing power of smart phones allows them to compete with hand-held devices and even with some home consoles. However, the lack of standardized gaming inputs on smart phones (other than the touch screen) limits the types of games that can be realized on them. This difference in input methods and therefore different games results in different demographics for the different platforms (cf. Amaro et al. 2016).

Social Networks and their Impact on Computer Games

According to Kushner (2011), (at least) with regard to North Americans, Nielsen Co. puts social networks and social games as the top two reported internet activities. The number of users of social games, such as *Car Town* (with eight million users), *Hero World* (with seven million users), or *Mafia Wars* (with 16 million users), cf. Laplante (2011), shows that social games motivate large numbers of humans to engage in collective online social activities.

Social Network Based Games

According to Kushner (2011), the game *Farmville* reported numbers as staggeringly high as 50 million users per month. *Candy Crush,* considered by, e.g., Amaro et al. (2016), to have been the most popular social game for a while, reported at times close to 11 million daily active users on Facebook. These games and their wide-spread play have finally changed the image of computer games in the public's opinion. This is unsurprising, considering that according to the reported numbers, at least one out of six people alive today is occasionally playing computer games in one way or another. The biggest hits seem to be so-called *social* games, games which are not only involving some social aspect but are also based on social web sites. This, combined with the fact that modern computers are found in almost every household in the first world, is probably the driving factor responsible for the mentioned explosion in user numbers.

The proliferation of computing power through everyday households is not new: already in 2003 David Anderson, the founder of the Berkeley Open Infrastructure for Network Computing (BOINC), declared that the majority of the world's computing power is now found in the millions of personal computers distributed all over the world (Rinaldi 2009). The applications that make use of this idle power and, more importantly, the assistance of humans interacting with the applications are shown to range from the search for extra-terrestrial life (*SETI@home*) over research for cures for cancer (Help Defeat Cancer, *HDC*) and AIDS *(FightAIDS@home*) to protein folding. Especially the game *Foldit,* originally designed to use the idle time of private computers to predict protein structures while providing the output of the progress as a screen saver has received large attention in the academic press (cf. Cooper et al. 2010; Khatib et al. 2011; Hand 2010). The application evolved into a game, where the computational effort is greatly assisted by human players insight and capabilities.

Multi-Player Network Games

Multi-player network games have existed for more than 30 years (Hasan 2010) and constitute a seizable part of today's (mobile) gaming landscape. Games like *EverQuest* earn/earned Sony an estimated $5 million per month from subscriptions alone, and this is certainly not the only

major game available: as Yan (2003) reports, online games such as *Ultima Online, Diablo II,* and Korea's *Lineage* have also achieved huge commercial success.

While engaging in games online and with others was already possible in the 1980s, the rise of the internet in the 1990s allowed for a major development in the gaming world. During the 1990s, the evolution of games went along with the internet and developed many systems which are still present and defined how online multi-player is today. While early games like *Doom* (1993) required the player to exchange IP addresses to play together, more and more comfortable ways were introduced to allow players to join together. With the widespread use of dedicated servers games like *Quake* (1996) introduced address lists which allowed the player to manage the servers. But the problem of requirement to know the IPs remained. This led to the development of server browsers like *QSpy* (later *GameSpy*) which operated as listing servers. Blizzard's *battle.net* service was first introduced in 1996 with the game *Diablo.* It provided – next to an integrated server browser – also a pre-game lobby system allowing players to team up before joining a game. Voice over IP (VoIP) services like *battlecom* or *Roger Wilco* allowed players to communicate more direct during the games.

Online Gaming Platforms

With the turn of the century the online multi-player concept made its way from PCs to consoles. Even though online services for consoles were already available from the 1980s on, starting with Ataris *GameLine* (1982) followed up by services from other companies like Sega with *SegaNet* (1994), they were only used to distribute games. One of the first online multi-player implementations for consoles was the *X-Band Modem* (1995). X-Band only supported a limited number of games on the *Super Nintendo Entertainment System* and the Sega *Genesis.* Ultimately the X-Band Modem was not successful and the company eventually folded in April 1997.

The first console to support online connectivity from the start was the Sega *Dreamcast* having a 56Kbps modem. Sega was ultimately failing and ended the production of the *Dreamcast* and thus of the *SegaNet.*

While the *Playstation 2* and the *GameCube* were provided with various types of network adapters, not making online multiplayer a core part of the systems, Microsoft launched the *XBox* with an included RJ45 network connector and, shortly thereafter, the *XBox Live* service. This service provided console players with various features like VoIP or friend lists next to the online multi-player which should become standard for online gaming services. With the success of the *XBox Live* service, the next generation of consoles saw a complete integration of online services, spawning the *PlayStation Network* as well as *Miiverse* (Nintendo).

Massively Multi-Player Games and eSports

The continuous spread of broadband internet connections and better infrastructure allowed also for bigger online games. While *World of Warcraft* is definitely not the first Massively Multi-player Online Role Playing Game (MMORPG), with (at its peak) 12 million users it is one of the biggest ones.

Better internet connections also brought the rise of the *eSports* scene. This more competitive aspect of online gaming saw the rise of a new genre: the *Mobile Online Battle Arena* games. Games such as *Dota 2* or *League of Legends* have prize pools reaching up to $24 million.

The Impact on the Gaming Industry

Security Requirements

The sheer order of magnitude and the nature of the distributed character of platforms have fundamentally changed security requirements for computer games. Yan (2003) argues that security, along with graphics and artificial intelligence, is emerging as an inherent design issue for online games; the dominant approach to copyright protection (which changed from protecting the information about the workings of the console to protecting the actual games) has been partly abolished again and is experiencing a reversal in some sense: the games depend less and less on the code that runs

the game and increasingly on the platform on which to run it (i.e., the ability to play against/with others). It should be noted that not all big multi-player online games are basing their business model on subscriptions though: for example, the online resource management game *Ogame* (Koutero et al. 2010) is free to play for anyone with internet access and (maybe because of this) has a large following of dedicated users which contribute to and maintain an extensive forum.

Monetization

The rise of popularity of online gaming can also be seen in numbers. A top seller of the online first person shooter genre *Call of Duty Modern Warfare 2* reported a starting day income of $310 million while the top income for the opening day of a blockbuster movie in cinema is *only* $119 million.

The latest big change in online gaming was not a technical change or a new feature but a change in the monetization of games. The introduction of micro-transactions allowed publishers to get a continuous stream of income during the life time of a game. Many features which used to be free or unlockable by game-play, like different skins or new characters, are sold for small amounts of real money. This business model let to a lot of controversies like the "*on disc"* DLC (downloadable content) from *Street Fighter X Tekken,* where extra characters, available for purchase separately, were already supplied on the originally purchased disc. Publishers and developers regularly claim that micro-transactions and DLC are needed to support further development and support for games. However, as in the case of *Street Fighter X Tekken,* many of their customers feel that this is inherently untrue since the content was already produced and the full code included in the original purchase (albeit not available in the game).

Advertisement

While from the 1990s and to the 2000s and 2010s almost every major announcement in the gaming world happened at trade shows like the *E3*, the rise of video streaming shifted this more and more to the social media platforms. This allowed the publishers to address their customers directly instead of only through the press. Even end customer trade shows like the *GamesCom* (350,000 visitors in 2017) do not even closely address the amount of people of a youtube video like the *Battlefield 1* trailer (having over 50 million views). Nintendo remarkably completely stopped attending the *E3* from 2013 onward and releases their own presentation video aside the trade shows.

With the rise of the popularity of the *Let's Play* genre game developers and publishers saw this as a new way to advertise their games. Companies like EA Games or Activision have dedicated events where *YouTubers* get invited to play their games and record videos. Remarkably, in 2017 Jason Blundell, Co-Studio Head of Treyarch (*Call of Duty*) made the decision to announce a big add in the bedroom of a *YouTuber* instead of at a trade show or through a special event, as it was standard in the industry until then.

While some companies see social media and especially *Let's Play* videos as free advertisement for them and rather rarely request a video take down, others like Nintendo have programs which allow them to participate in the monetization while exercising higher control over what is broadcasted.

Social media did not only allow the publishers to address their customers more directly but also the other way around. From expressing aesthetic dislikes (e.g., in the case of the (*Call of Duty Warfare*) trailer which as of December 2017 has over 3 million dislikes over technical feedback and game mechanic changes to even changing the aspects in the monetization (such as the removal of the money auction house for (*Diabolo 3*) or the 2017 (*Battlefront 2*) controversy) gamers are using all of the existing social media platforms to tell the developer what they like and what they don't like.

Conclusion

In the last decade, and due to the pervasive nature of mobile devices, there has been increased interest in the use of this technology for all types of applications, including computation intensive optimization programs (e.g., Branki et al. 2008; Bitterberg

et al. 2009, 2011). This indicates that the average handheld device is computationally capable to serve as a platform for educational (Hildmann and Hildmann 2012a, b) games, for games-based evaluation and assessment tools (Hildmann and Boyle 2009; Hildmann 2013), or for the gamification of behavioural interventions (Bitterberg et al. 2008; Hildmann and Hirsch 2008; Al Houqani et al. 2013; Hildmann et al. 2009).

Sociality of Digital Games

Mikhail Fiadotau

Synonyms

Multiplayer games; Social games

Definition

The sociality of digital games encompasses a diverse range of interactions involving both players and their in-game representations. These interactions may have both positive and negative effects on players' real-life social relationships. They can also enable identity play and self-expression, as well as develop empathy in players.

Introduction

There exists a perception in the popular imaginary that digital games negatively affect players' social skills (Kowert and Oldmeadow 2014). Existing research, however, has not reached a consensus on the matter. While some researchers have found that playing even multiplayer games can be a solitary and isolated experience (Ducheneaut et al. 2006), others have reached the opposite conclusion, discovering, for example, that playing massively multiplayer online games (MMOs) can increase older adults' social interaction (Zhang and Kaufman 2015), or that some games can

promote empathy and decrease schadenfreude in players (Greitemeyer et al. 2010).

Importantly, the framing of this discussion is based on a restrictive, normative view of sociality as something based on people's face-to-face interactions. Such a view does not account for the complexity of manifestations of sociality in and around digital games. This entry outlines some of these manifestations.

Interpersonal Sociality in Games

Games as Environments/Media

Multiplayer games create environments where avatars controlled by players interact. As avatars do not need to correlate with players' real-life identities in terms of gender, race, faith, and even species, this opens up rich possibilities for self-expression. MMOs thus often become spaces of identity play, allowing players to "express themselves in ways they may not feel comfortable doing in real life" (Cole and Griffiths 2007) by constructing an avatar different from their physical selves in appearance, gender, and age, as well as behavior. Identity play is also often richly social, leading to avatar conversations, friendship, and even marriage (including same-sex marriage between avatars controlled by players from countries where actual same-sex marriage is legally problematic, such as China; see Li et al. 2008).

Multiplayer environments can, however, produce very different kinds of sociality. Some in-game virtual communities emerge spontaneously for the purpose of a single match or tournament only, as in the case of the Swedish *Armed Forces' Team Test* (2010), where four anonymous participants are formed into a team which then has to face numerous challenges that require teamwork to complete. Virtual communities can also be recurrent if players return to the same, if constantly evolving, world every time they enter the game, as in *World of Warcraft*.

In-game interactions between avatars are not isolated from players' real lives. According to Cole and Griffiths (2007: 582), 39.3% of online gamers reported discussing "sensitive issues with their online gaming friends that they would not discuss with their real life friends," 42.8% "had met with online friends in real-life situations," and 10.1% "had developed a physical relationship with another player," substantiating the idea that the dichotomy between real-life and virtual sociality is a false one (Lehdonvirta 2010). This is further evident when considering the example of *CitiTag* (2004), a mixed reality mobile game which tracks its players' geographical location and spontaneously assigns people into competing teams based on the whereabouts of their physical selves in order to facilitate social interaction. Professional esports supports the same point from a different angle, as it enables real-life inter- and intrateam interaction (Freeman and Wohn 2017), as well as spectator play.

On the other hand, as Ahlstrom et al. (2012) point out, excessively playing MMOs can harm one's existing real-life relationships, for example, negatively affect marital satisfaction, leading some spouses of MMO players to identify as "gamer widows" (Lianekhammy and Van De Venne 2015). MMO communities are also known to struggle with cyberbullying and toxic behavior, despite having provisions for reporting and penalizing it, which are often underutilized (Kwak et al. 2015). One notable problem is sexism. In Brehm's (Brehm 2013) study, for example, 63.6% of female *World of Warcraft* players reported experiencing sexist behavior in the game. The hierarchical structure of many multiplayer games can also lead to cronyism and power abuse (Meachem 2012).

Games as Environments/Media

A different social dynamic is when interpersonal interaction arises *around* a digital game, not inside it. One manifestation is player activity on forums and social media, where strategies, experiences, and ideas are shared, often using a separate nickname from their in-game avatar or (on social media) disclosing their real name. These groups of players can be seen as "communities of interest," as they "bring together participants who interact extensively about specific topics of interest" (Armstrong and Hagel 2000: 85) without

necessarily getting to know each other outside these topics. In many game-related online communities, collaborative content production also actively takes place, making them "communities of practice" (Wenger 1998). Modding communities, which revolve around modifying or creating alternative versions of a digital game (Sotamaa 2010), are a prominent example.

Playing digital games together with one's friends or family is another type of activity whose essence lies not in the content of the game itself but in the social interactions around it, as well as the shared experience which play produces (Cole and Griffiths 2007; DiSalvo and Bruckman 2010). Often, such settings lead to "vicarious play," whereupon some of the players participate in the play mentally and verbally, without actually using game controls (De Schutter and Vanden Abeele 2010). The increasingly popular "Let's Play" videos on platforms such as YouTube often seek to replicate this feeling of playing together, though with an emphasized performative dimension (Glas 2015).

Parasocial Interactions in Games

Like any art form, digital games often seek to elicit an emotional response from the player by getting them involved in parasocial relationships, i.e., "relationship[s] between media users and media figures (from celebrities to fictional characters)" (Giles 2002). Mourning the death of a hero, resenting the antagonist, or suffering from a "breakup" with the protagonist after completing a game series are all forms of parasocial relationships. However, what is more specific to the medium of digital games is that characters can react to the player's input and "talk back," enabling "paracommunication" (Hartmann 2008) between the player and the character. Coulson et al. (2012) have concluded that "people form real and authentic emotional attachments to virtual characters," suggesting that parasociality may not be experientially different from regular sociality. Greitemeyer et al. (2010) provide further evidence of that by demonstrating that playing "prosocial games" can increase players' empathy.

Conclusion

Sociality within and around digital games has a diverse range of manifestations, which challenges the simplistic, yet still common, discourses of games being anti- or asocial. However, in order to understand the complexity of the social effects of digital games, a broader view of sociality needs to be adopted than the prescriptive notion of sociality as being based on face-to-face interactions between people.

[2]Vincennes University, Vincennes, IN, USA

Synonyms

Platformer

Definitions

Platformer A game genre where a character must maneuver through obstacles by jumping, climbing, etc. to reach a goal.

Sonic Adventure 2 - A Platform Game

Sonic Adventure 2 is a platformer that was developed by Sonic Team and published by Sega as an anniversary title in the Sonic the Hedgehog series. It has been released three times on five different consoles: the original release on the Sega Dreamcast on June 20, 2001, Sonic Adventure 2: Battle, a remake of the original with updated lighting and additional content released on Nintendo Gamecube on February 11, 2002, and Sonic Adventure 2 HD, which was released on PlayStation 3 and Xbox 360 on October 2, 2012, and PC on November 19, 2012. It is primarily single player with a story mode featuring three stories, a level select to replay levels for better times or to get more collectibles, and several other minigames. There is also a multiplayer mode where you can race through edited levels. It was given a rating of E10+, higher than Sonic Adventure, due to the mention of some characters dying and an overall darker plot (Entertainment Software Rating Board).

The game's target audience was primarily teenagers and up, as shown by the darker and more complicated story compared to previous games in the series. It is the followup to 1998's Sonic Adventure, continuing and enhancing the newfound 3D style. It was created to celebrate the 10th anniversary of the franchise and introduces two new major recurring characters to the series, Rouge the Bat and Shadow the Hedgehog. The story is split up into two main stories – Hero and Dark – and one unlockable story that ties it all together, the Last story. It involves the series protagonist, Dr. Eggman, unsealing Shadow from stasis to get his assistance in taking over the world. Sonic, mistaken for Shadow by the police, gets wrongly apprehended but manages to escape with help from his friends, Tails and Knuckles. They then figure out Eggman's plans and work together to end his plan. Major characters include Sonic, Tails, a fox who is Sonic's best friend and sidekick, Knuckles, an echidna who guards a powerful gem called the Master Emerald. These three make up the Hero team. The Dark team includes Shadow, an artificial life form known as the Ultimate Lifeform, Dr. Eggman, an evil genius who wishes to control the world using robots and his own intelligence, and Rouge the Bat, a treasure hunter hired as a government spy to covertly work with Eggman to uncover more information about Shadow. Other minor characters include Amy Rose, a pink hedgehog who follows Sonic everywhere he goes, and the President, who rules over the United Federation and attempts to negotiate with Eggman.

The game includes 32 stages, divided up by the six characters. Sonic has seven stages, with one being unlockable by getting all collectibles, Tails has five stages, with one being a kart driving stage, Knuckles has five stages, Shadow has four stages, Eggman has five stages, and Rouge has five stages, one being a kart stage. There is also one last stage, Cannon's Core, which serves as the final level in the whole game where you switch between all characters except for Shadow. There are also boss and rival stages where each character will fight a large enemy or their counterpart from the other team.

The game has three different play styles with two characters assigned to each style. The first are the running stages, where the goal is to get to the end of the stage, either defeating or ignoring enemies along the way. These stages are played as either Sonic or Shadow. The next are shooting stages, where the characters get into a mech walker with the goal of destroying as many enemies as possible then make it to the end of the stage. They are much slower, with more emphasis on defeating enemies than going fast. These are played as either Tails or Eggman. The final style are treasure hunting stages, where the goal is to find three of a specific object, typically being Master Emerald shards, but can also be keys or other gems. These are played as either Knuckles or Rouge.

The public opinion of the game varies wildly, like many of the other 3D Sonic games. On one

hand, many people call it the best example of 3D Sonic gameplay, having one of the more memorable stories in the series and introducing a strong character in Shadow. Others speak more negatively of the game, citing a particularly bad camera in some sections, gameplay other than the running stages being either frustrating or not fun at all, and the unequal division of stages; one of the most important characters, Shadow, only got four stages. There are a few major plotholes that people cite as proof that the story is not very good. For example, the premise of one of Rouge's levels is completely pointless and avoidable (Metacritic). Eggman orders her to break into a government vault in order to steal three gems to proceed with their plan. However, being a double agent, there is no reason she would have had to break in, when she could have just requested the emeralds and make it look like she broke in. Another point of contention is the controls. Actions, such as shooting, picking up objects, somersaulting, and other maneuvers are all mapped to one button, with the longer you hold it down determining the action you take. This can become very clumsy, leading you to roll off a ledge when you are trying to interact with another object, wasting precious time and potentially costing you a life. There are several fixes for this, all involving using one of the several other buttons available.

Overall Sonic Adventure 2 is a game that has a few flaws, but has stood the test of time and holds a place in the hearts of fans for being a solid platformer.

Sonic Interactions in Virtual Environments

Stefania Serafin
Multisensory Experience Lab, Aalborg University Copenhagen, Copenhagen, Denmark

Synonyms

Audio design; Sound and music computing; Sound synthesis

Definitions

Sonic interaction design is defined as the study and exploitation of sound as one of the principal channels conveying information, meaning, and aesthetic/emotional qualities in interactive contexts. This field lies at the intersection of interaction design and sound and music computing.

Introduction

In recent years, the availability of low-cost head-mounted displays has enhanced the interest toward immersive sound experiences. Investigations on 3D sound in the context of virtual reality (VR) are not a novel topic (Begault and Trejo 2000). In an interactive immersive experience, sound can direct the attention of the user and enhance the sense of presence (Hendrix and Barfield 1996; Nordahl and Nilsson 2014; Serafin and Serafin 2004) and the ability to move users by creating interactive time-varying experiences (Nordahl 2006). The auditory modality possesses unique features. Unlike its visual counterpart, auditory perception is always turned on, since one cannot close the ears. Thus, this sensory channel always flows with information about the surrounding environment, regardless of whether one is attentive to this information or not (Gilkey and Weisenberger 1995). Visual perception is superior in terms of spatial resolution, but it is

inherently directional. Our limited field of view entails that one has to turn the head or body in order to perceive the surrounding environment. Auditory perception, on the other hand, is omnidirectional (Pope and Chalmers 1999). Moreover, as highlighted, for example, by Larsson and his colleagues (Larsson et al. 2010), auditory cues are inherently temporal in nature. A sounding event is by definition an unfolding event. In sum, it appears that auditory displays constitute a relatively inexpensive and valuable component of VR systems intended to represent multimodal virtual spaces and elicit a sensation of presence in these spaces. In the past decades, several methods have been developed for the automatic generation of sound by making use of techniques developed in computer graphics, such as texture mapping/synthesis (Takala and Hahn 1992) and rigid body simulations (Van Den Doel et al. 2001). These methods make it possible to create realistic sound related to objects in motion and depending on the geometric relationship between the receiver and the sound source. Sound synthesis and rendering are slowly becoming an important research field even in virtual reality.

Several research questions, however, remain open, especially when 3D sound is embedded into ecologically valid interactive multisensory experiences. In these situations, results from investigations of the role of 3D sound in static unisensory experiences might not still hold as valid.

In this article an overview of the state of the art of immersive sound rendering is provided. Although immersive sound can be delivered through a speaker setup or headphones setup, here the focus is on sound rendering through headphones, since it is the hardware solution available with state-of-the-art consumer head-mounted displays. Headphone-based sound rendering makes it possible to completely control the sound arriving at each ear. In addition to offering more precise control of binaural cues, unwanted sounds such as echoes and reverberation are kept from reaching the ears of the listener. However, this comes at a price since the headphones may be experienced as intrusive by the user (Shinn-Cunningham and Shilling 2002).

Immersive Sound for Virtual Reality

A complete immersive sonic simulation needs to take into account action sounds, environmental sounds, sound propagation, and binaural rendering. Action sounds are those sounds produced by the user which need to change according to movements. One of the essential elements of sound events in VR that distinguishes them from film is the importance of interactivity: actions of the users such as walking, hitting, throwing, etc., often generate sounds. Ballas (2007) refers to such action-based sounds as self-sounds and describes them as sounds that are produced by one's own body or body movements, which need to vary according to the action of the user. Environmental sounds are those sounds produced by objects in the environment, as well as the soundscape of the space. Sound propagation represents the simulation of the acoustics of the space, either a closed space such as a room or an open space. Binaural rendering relates to how the sound reaches each of our ears and allows us to perceive sounding objects as placed at a specific azimuth (horizontal direction), distance, and elevation. In the literature the term, virtual acoustics has been used to cover the three main elements of the system: source modelling, room acoustics modelling, and receiver modelling (Savioja et al. 1999). One of the first complete virtual acoustics systems that includes all three elements is the system developed at Helsinki University of Technology (Huopaniemi et al. 1996). In a traditional audio design pipeline, a monophonic sound is synthesized, and then it is spatialized, e.g., virtually positioned in its environment.

Simulating sound events for VR imposes additional challenges as opposed to sound events for film or other interactive media such as games. One essential difference between immersive and non-immersive interactive media is the fact that users are fully surrounded by the environment. In these situations sound can help to direct the attention of the user or enhance the sensation of place and space. In this article all the elements that produce an immersive sonic experience are examined.

Action Sounds

For action sounds and environmental sounds, here the focus is on sound synthesis algorithms that have been used in real-time contexts, for their relevance in virtual reality simulations. While the computer music community has a long tradition of using real-time sound synthesis, specifically for the simulation of musical instruments (see, e.g., (Morrison and Adrien 1993; Smith 1992; Välimäki and Takala 1996; Cook 2002)), this is not the case for virtual reality.

One of the first examples of the use of physics-based models for interactive audiovisual environment is the work presented in Van Den Doel et al. (2001). Here the authors present a simulation of different solid interactions such as impact, friction, rolling, and using a combination of physics-based simulations and recordings extracted from real objects. The authors use a synthesis technique known as modal synthesis (Adrien 1991). The main principle behind modal synthesis is the decomposition of vibrating objects in their modes, e.g., the resonances of the system. Each mode can be simulated as a mass-spring system or an exponentially decaying sinewave.

In O'Brien et al. (2002), a real-time technique for generating realistic and compelling sounds that correspond to the motions of rigid objects is presented. In this case the actions are not necessarily actions of the user in the environment but actions between objects present in the simulation. By numerically precomputing the shape and frequencies of an object's deformation modes, audio can be synthesized interactively directly from the force data generated by a standard rigid body simulation. This approach allows to accurately model the sounds generated by arbitrarily shaped objects based only on a geometric description of the objects and a handful of material parameters.

In Avanzini et al. (2005), the authors presented some efficient yet accurate algorithms to simulate frictional interactions between rubbed dry surfaces. The work is based on the assumption that similar frictional interactions appear in several events such as a door squeaking or a rubbed wineglass. For this reason, the same simulation algorithm can be used with different parameters adapted to the different objects interacting. In Avanzini and Crosato (2006), an algorithm similar to the one presented in Avanzini et al. (2005) is adapted to simulating impacts in multimodal applications.

Environmental Sounds

The class of environmental sounds covers a large variety of sounds since it relates to all events occurring in the listener's surroundings. Consequently, a generic definition of such sounds cannot be easily found (Verron et al. 2010).

One of the first researchers interested in investigating environmental sounds from a simulation perspective was Gaver (1993). He proposed a taxonomy of environmental sounds supported by the physics of sound events.

Sound Propagation

Sound propagation refers to the simulation from the sound-producing object to the ears of the listener. A complete survey of methods for sound propagation in interactive virtual environments is described in Funkhouser et al. (2003). A primary challenge in acoustic modelling of sound propagation is the computation of reverberation paths from a sound source to a listener (receiver) (Kleiner et al. 1993). As sound may travel from source to receiver via a multitude of reflection, transmission, and diffraction paths, accurate simulation is extremely computationally intensive.

One simple approach to simulate the space is by capturing the so-called impulse response and convolving it with the original dry signal (Begault and Trejo 2000). This method is simple but lacks flexibility. Therefore several geometric, wave-based, and hybrid methods have been proposed for sound propagation modelling. Wave-based techniques can be mathematically and computationally expensive, so alternative efficient solutions need to be investigated in order to use these techniques in real-time simulations. In James et al. (2006), preprocessing of analogous

global sound radiation effects is investigated for a single vibrating object, showing that expensive linear acoustic transfer phenomena can be largely precomputed to support efficient real-time sound synthesis.

An efficient and accurate sound propagation algorithm is also proposed in Raghuvanshi et al. (2009). The proposed technique relies on an adaptive rectangular decomposition of 3D scenes to enable efficient and accurate simulation of sound propagation in complex virtual environments. In Savioja (2010) a wave-based simulation is proposed, which combines finite difference methods together with computation on the GPU. In Mehra et al. (2014), an efficient technique based on precomputing a set of pressure fields due to elementary spherical harmonic (SH) sources using a frequency domain wave-based sound propagation technique is proposed. An extension of the technique is proposed in Mehra et al. (2015), where an interactive wave-based sound propagation system for efficiently generating accurate and realistic sound is proposed. The approach is based on a recent numerical solver for the acoustic wave equation called the equivalent source method (Mehra et al. 2013).

In Mehra and Manocha (2014), a set of efficient wave-based propagation techniques for VR applications that can handle large scenes and directional sound sources and generate spatial sound are presented. The proposed techniques have been used to demonstrate realistic acoustic effects, such as diffraction, high-order reflection, interference, directivity, and spatialization, in complex scenarios.

Geometric techniques such as the one proposed in Funkhouser et al. (1998) use precomputed spatial subdivision and beam tree data structures to enable real-time acoustic modelling and auralization in interactive virtual environments. Hybrid solutions combining wave-based and geometric techniques have been proposed in Yeh et al. (2013). Here numerical wave-based techniques are used to precompute the pressure field in the near-object regions and geometric propagation techniques in the far-field regions to model sound propagation.

Efficient simulations of reverberation in outdoor environments are a field with limited research results. Recently, however, an efficient algorithm to simulate reverberation outdoor based on a digital wave guide web is proposed (Stevens et al. 2017). The design of the algorithm is based on a set of digital wave guides (Smith 1992) connected by scattering junctions at nodes that represent the reflection points of the environment under study. The structure of the proposed reverberator allows for accurate reproduction of reflections between discrete reflection points. This algorithm extends the scattering delay network (De Sena et al. 2011) proposed for reverberation in computer games.

Binaural Rendering

Binaural hearing refers to the ability of humans to interpret sounds arriving at both ears into complex auditory scenes.

Shinn-Cunningham and Shilling (2002) distinguish between three types of headphone simulation, namely, diotic displays, dichotic displays, and spatialized audio. The first simply refers to the display of identical signals in both channels, something which gives the listener the sensation that all sound sources are located inside the head (Shinn-Cunningham and Shilling 2002). Secondly Shinn-Cunningham and Shilling (2002) refer to stereo signals that just contain frequency-dependent interaural intensity or time differences as dichotic displays. The two authors describe this type of display as very simply since the effect can be achieved by scaling and delaying the signal arriving at each ear. Just as diotic displays, this does not enable proper spatialization of the sound sources since listeners may get the feeling that the sounds are moving inside the head from one ear to the other (Shinn-Cunningham and Shilling 2002). Finally, spatialized sound makes it possible to render most of the spatial cues available in the real world. This is made possible by the use of various cues, such as provided by the head-related transfer function (HRTF), sound reflections in the

surrounding space, or dynamic modifications of these cues caused by head movements (Kendall 1995). Several current research efforts are examining the development of HRTF personalization for individual users of a virtual audio display.

In Meshram et al. (2014), a technique to obtain personalized HRTFs using a camera is proposed. The technique combines a state-of-the-art image-based 3D modelling technique with an efficient numerical simulation pipeline based on the adaptive rectangular decomposition technique (Raghuvanshi et al. 2009). In Geronazzo et al. (2016), the SelfEar project is presented, aimed at low-cost acquisition and personalization of HRTFs on mobile devices.

An important component of the modelling of sound propagation for VR is the spatialization of the room impulse response (RIR) for directional listeners. This involves convolution of the listener' s head-related transfer function (HRTF) with the RIR to generate a spatial room impulse response (SRIR) which can be used to auralize the sound entering the listener's ear canals. Previous approaches tend to evaluate the HRTF for each sound propagation path, though this is too slow for interactive VR latency requirements.

In Schissler et al. (2017), a new technique is presented for computation of the SRIR that performs the convolution with the HRTF in the spherical harmonic (SH) domain for RIR partitions of a fixed length.

Applications

All the examples considered until now have focused on the technological side of immersive audio, from creating sound events, to binaural sound, and sound rendering in space. In the following the focus is on the content and design of different recently developed immersive experiences where sound plays a fundamental role.

In Summers and Jesse (2017) and Summers et al. (2015), the authors discuss specific immersive and aesthetic auditory design techniques as applied to create full-motion, multi-participant virtual reality game experiences for live commercial location-based entertainment (LBE) installations. The authors introduce fundamental design considerations and emerging best practices used in spatially responsive virtual reality audio design and implementation and complement these with practical examples that embrace the complexities of immersive and aesthetic audio design in virtual reality. The design considerations are based on the understanding that audio has the potential to craft the story elements of a product, control the pacing of an experience, enforce the narrative, elicit and influence emotion, create mood, shape perception, and reinforce the way people experience characters.

In Janer et al. (2016), audio signal processing and VR content are combined to create novel immersive experiences for orchestral music audiences. In VR, the auralization of sound sources of recorded live content remains still a rather unexplored topic. In this article a multimodal experience is built, where visual and audio cues bring a sonic augmentation of the real scene. In the particular scenario of orchestral music content, the goal is to acoustically zoom on a particular instrument when the VR user stares at it. The ultimate goal is to improve the learning aspects of music listening, either for education or for personal enrichment.

Virtual reality musical instruments are also a field where naturally physics-based sound modelling and rendering play an important role. For a recent overview of virtual reality musical instruments, the work presented in Serafin et al. (2016) is a good reference.

Carefully designed sounds can be used to reproduce the acoustics of specific spaces, such as the Notre-Dame Cathedral (Katz et al. 2017). In this particular situation, a computational acoustic model of the acoustics of the space was captured and reproduced to be utilized in an immersive VR experience.

Finally, assisted listening and navigation for partially or fully visually impaired users are an example of an important application of interactive sound rendering for virtual environments. As an example (Valimaki et al. 2015), an overview of the use of augmented audition for navigation is presented.

Conclusion

In this article the author presented an overview of the state of the art of interactive sound rendering from immersive environments. As shown in this paper, in recent years several progresses have been obtained in the three different elements of the sound design pipeline, e.g., source modelling, room acoustics modelling, and receiver modelling. From the point of view of source modelling, many sound events have been synthesized, and real-time simulations exist. However, these simulations have not yet been adopted in commercial software engines usually adopted in the VR community. These can be due to the fact that the quality of the simulations is not high enough, so professionals still prefer to rely to recordings, despite their limitations such as the fact that they do not show the same flexibility as simulations.

Room acoustics modelling has also shown several progresses, and efficient algorithms combined with increase computational power make such models available in real time. Further research is needed to adapt these models to several environments, from outdoor to indoor, and to better simulate the acoustic sensation of moving in different spaces such as a tunnel, an arch, etc.

Finally, an active field of research is the capturing and implementation of personalized HRTFs. While listening tests in static environments have shown that subjects have a better sensation of space with personalized HRTFs, it is not yet investigated whether high-fidelity personalized HRTFs are needed in complex virtual environments where several independent variables are present such as the visual elements of the environments and the action of the user.

Sound Spatialization

Michele Geronazzo
Department of Architecture, Design, and Media Technology, Aalborg University, København, Denmark

Synonyms

Auralization; Binuaral headphone reproduction; Loud-speaker reproduction; Room acoustics; Room response equalization; Spatial room acoustic; Spatial room impulse response; Virtual acoustics

Definitions

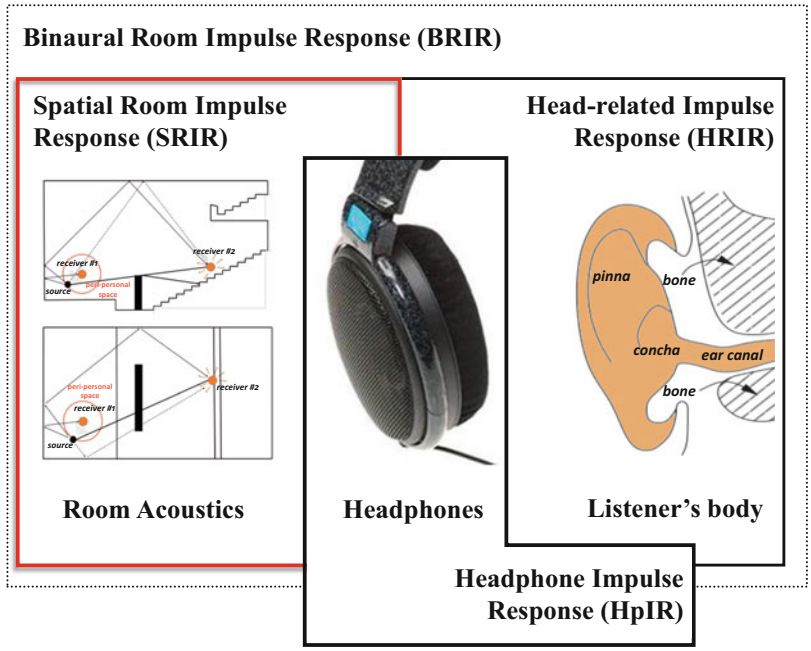
The general term sound spatialization refers to a reproduction system and their algorithms that combined together provide a real-time and interactive rendering or auralizaion for an immersive sonic experience in virtual reality scenarios. Four main aspects can be considered: (i) physics-based simulation of sound sources, (ii) their propagation in space together with (iii) binaural rendering to simulate user acoustics in the listening space or sound-field en-coding/decoding for multiple loudspeaker reproduction, and finally (iv) the technological mediation for listening through headphones/loudspeakers and for interaction trough motion capture. Finding the trade-off between accuracy and perceptual plausibility is the key aspect while considering always evolving hardware solutions for such complex simulations.

Introduction

A high fidelity but efficient sound simulation is an essential element in immersive virtual reality (VR). Continuous advances in hardware and software technologies fosters interaction between virtual sounds and humans in rendering experiences with increasing level of realism and presence.

From the literature, one can refer to the general term auralization that covers the three main components for sound spatialization (Savioja et al. 1999): source modeling, room acoustics modeling, and receiver modeling. A schematic view of those aspects can be seen in Fig. 1.

It has to be noted that many algorithms for virtual acoustics are computer vision and graphics rendering techniques (see entry "▶ Computer Vision") that are adapted to take into account for sound generation and propagation. Some examples are texture mapping/synthesis (Takala and Hahn 1992), beam tracing (Funkhouser et al. 1998), and rigid body simulations Van Den Doel et al. (2001), allowing the synthesis of realistic



Sound Spatialization, Fig. 1 High-level acoustic components for VR auralization with focus on spatial room acoustics and headphone reproduction

sonic interaction of objects in motion with a geometric relationship in space.

On the other hand, a perceptually plausible and efficient auralization is forced to be preferred to an authentic rendering due to the limitation in memory and computational power related to low latency constraints. This trade-off is complex and challenging because, especially in VR, real-time constraints involve a multimodal system, thus requiring resources shared with graphics, sensors, application logic, and high-level functionality (e.g., artificial intelligence).

Reproduction

Immersive sound spatialization can be achieved through a speaker setup or headphones setup, with technical differences in the encoding phase and radical differences in perception for listeners. Entry "Virtual Reality: Headphones" discusses headphones sound playback that is the hardware solution available and easily integrated with head mounted displays (HMD) at customer level. In the following, a brief overview of both approaches is provided.

Headphone Reproduction

One of the main advantage of headphone-based reproduction is the complete control of sound synthesis and binaural cues arriving at each ear (left and right channels); high level of isolation from external and noisy environmental sounds, e.g., echoes and reverberation, in listeners' can be obtained by ear occlusion and noise-canceling technologies.

However, headphones may be experienced as intrusive by the user at the expense of naturalness and externalization of the listening experience, causing the so-called in-head localization where stimuli are heard inside the head, thus interfering with the natural outside-the-head localization of surrounding space (Shinn-Cunningham and Shilling 2002). Headphone-induced spectral coloration can be reduced by carefully following product design criteria and ad-hoc equalization algorithms with the aim of minimizing artifacts in the auralization.

Auralization with headphones requires head-related transfer function (HRTF) encoding and interpolation in a suitable functional basis, like in the spherical harmonic (SH) domain. A HRTF spatial grid of 4 5° spacing in both azimuth and

elevation with decreasing density above the head leads to a perceptually optimal representation for HRTF filters that could be convolved with partitioned block algorithm providing a compromise between computational efficiency and latency (Välimäki et al. 2016).

Loudspeaker Reproduction

In a loudspeaker reproduction, the rendered sound-field is completely extra-aural, thus naturally incorporating user acoustics in the so-called sweet-spot, i.e., the optimal listening area, which varies in size among techniques. Two main approaches can be considered (see Spors et al. 2013) for a detailed review on this topic):

1. Panning with level differences and/or time delays
2. Sound-field synthesis

The most common example of the first approach is the two-channel stereophony where the so-called panning law determines level/time differences in two loud-speakers in order to render virtual sources. The works by Pulkki formalize the vector-based amplitude panning in a multiple loudspeaker setup (Pulkki et al. 2018).

Sound-field synthesis employs a large number of loudspeakers to synthesize a virtual sound field within a listening area. These multiple channels are usually arranged at ear level as linear, circular, or spherical arrays defining the distribution of monopole sources used to compute the virtual secondary sources and the pressure field at an open area surface with a desired spatial sampling, i.e., aliasing frequency. Examples of such approach are wave-field synthesis, higher order ambisonics and their derivatives. It is relevant to note that human perception plays a critical role also in the design of the loudspeaker configuration and reproduction algorithms in order to guarantee a satisfactory perceived audio quality.

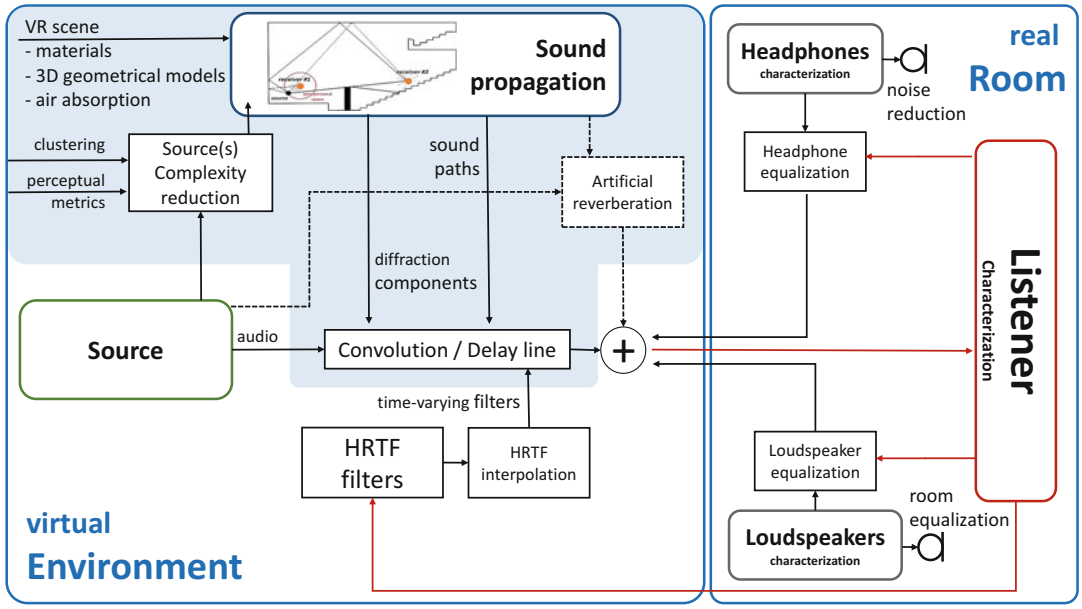
A critical aspect of loudspeaker reproductions lies in the acoustical properties of the playback environment that require room response equalization (RRE) algorithms able to remove echos and spectral distortions in the virtual sound field. Knowledge of single- or multiple-points of the room impulse response (RIR) inside the listening area is necessary to determine the most appropriate inverse filtering design able to compensate reflections and resonances of the environments (see Bharitkar and Kyriakakis (2006) for a review in this topic). Adaptive equalization is thus performed by optimizing signal processing approaches able to take into account the time-varying nature of the system, e.g., least-square solution, frequency warping, and multiple-input/multiple-output (MIMO) inverse theorem methods, to name but a few.

Auralization

The common and simple approach to provide an approximation of an acoustical space is by using a static RIR which could be convolved with an original dry signal; unfortunately, this method lacks of flexibility and it is inappropriate for VR. Rendering sound propagation for VR requires the spatialization of the directional RIR in the spatial room impulse response (SRIR).

Interactive auralization forces algorithms to cover most of the psychoacoustic effects in localization and timbre distortion due to dynamic changes of the active listening experience, thus defining memory and computational requirements (see Fig. 2 for a schematic block diagram). Given an encoding representation of the sound field, interactive VR latency requires the computation of SRIR in a convenient way: for instance, Schissler et al. (2016) performed the convolution in the spherical harmonics domain for HRTFs, sharing similar aspects to technologies for multichannel surround system such as high-order ambisonics, wave-field synthesis, and directional audio coding.

Sound propagation simulates the acoustics of the space, either a closed space such as a room or an open space surrounding the listeners (a complete survey in interactive virtual environments is provided in (Välimäki et al. 2016). One of the main challenges is the accurate modeling of sound propagation which is computationally intensive due to the multitude of reverberation



Sound Spatialization, Fig. 2 Block diagram of a typical system for sound spatialization and auralization. Both headphone and loudspeaker reproduction are displayed in the same diagram

paths from virtual sound sources to listener ears/listening area.

Perceptually motivated algorithms provide the control of computational resources, i.e., CPU and GPU processing, for SRIR computation, allowing a flexible scaling of aural complexity. For this reason, algorithms for dynamic spatialization of room acoustics allow immersion and externalization of a multiple sound source scenarios with configurable geometric complexity and implemented acoustic effects (i.e., order of reflections, diffraction, and scattering). Diffracted occlusion and sound propagation of early reflections should be coherently rendered in order to implement a perceptually plausible auralization.

Sound propagation modeling can be classified in three main approaches:

- Geometric methods, involving a high frequency approximation of sound propagating in the form of rays
- Wave-based methods, solving underlying physical equations
- Hybrid methods, mixture of approaches

Geometric Methods

Geometric techniques precompute spatial subdivision and beam tree data structures in order to provide real-time acoustic auralization of static sound sources. Modern algorithms support moving sources relying on an efficient ray-tracing which is shared with computer graphics (CG) (Cao et al. 2016); finding intersections between rays and geometric primitives in a 3D space allows the optimization of supporting data structures in computational cost and memory for a perceptually coherent auralization.

Wave-Based Methods

Wave-based methods are computationally expensive, requiring efficient solutions for real-time VR rendering. Savioja (2010) proposed a wave based simulation, combining finite difference methods and computation on the GPU. Mehra et al. (2015) described an interactive sound propagation system based on equivalent source method (ESM) for realistic outdoor sounds. This method extends previous researches where pressure fields are precomputing based on elementary spherical

harmonic (SH) description of the wave-based sound propagation in the frequency domain; high-dimensional acoustic field is compressing and allocated in memory for dynamic changing of sources/listener position and source directivity.

Hybrid Methods

Many hybrid solutions combining wave-based and geometric techniques exist. A valuable example is the work by Yeh et al. (2013) which proposed the precomputing of the pressure field in the near-object regions with numerical wave-based techniques and the modeling of sound propagation in the far-field with geometric propagation techniques.

Conclusions

Culling of inaudible reflections, limiting, clustering, and projecting reflections in the egocentric listener frame are required in order to increase the perceptual plausibility of the sound spatialization while keeping under control memory and computational cost (Hacihabiboglu et al. 2017).

The encoding of a virtual sound field require the parametrization of the perceptual fields in descriptors such as propagation delays, loudness, and decay times, ready to be quantized and compressed; the final aim of auralization techniques should be to find practical solutions on large, complex interactive scenes with millions of polygons (Raghuvanshi and Snyder 2014).

Finally, it has to be noticed that auralization of virtual outdoor environments is a challenging issue. Efficient algorithms rely on digital waveguide web connecting scattering junctions at nodes that represent discrete reflection points in the environment (Stevens et al. 2017). These algorithms extend the scattering delay network approach which was developed with particular attention to computer games (Hacihabiboglu et al. 2017).

Definitions

Audio spatialization is referred to an audio processing algorithm by which one is able to create an impression of a virtual sonic source positioned in a specific location in a virtual context.

Introduction

Spatial audio plays a vital role in the design of a variety of multimedia presentations, especially virtual and augmented reality games. The brain processes sensory stimuli from both ears to analyze the surrounding sonic scene and detect the nature and position of sound sources as objects or as ambient sounds (Jan Schnupp and King 2012; Blauert 1996). The brain also analyzes the acoustical signature of the environment and makes inferences about the size of the environment and the materials comprising the environment.

Spatial audio algorithms provide mechanisms for composers and sound designers to consider such auditory cues when planning the experience and the narrative of an XR (augmented/virtual reality) game or a multimedia presentation. In traditional theatrical and cinematic contexts, the proscenium, camera angle, and lighting design all provide visual cues to define the focal point of the narrative and lead the attention of the audience members. Analogously, in the context of a game in which the player has the freedom to look and move around in three dimensions, 3D spatialized audio cues play an important role in supporting the narrative of the game and guiding the player's focus. This entry discusses a number of sound design strategies and audio spatialization techniques which are often used in audio production for games and other multimedia.

Sound Design and Spatial Audio

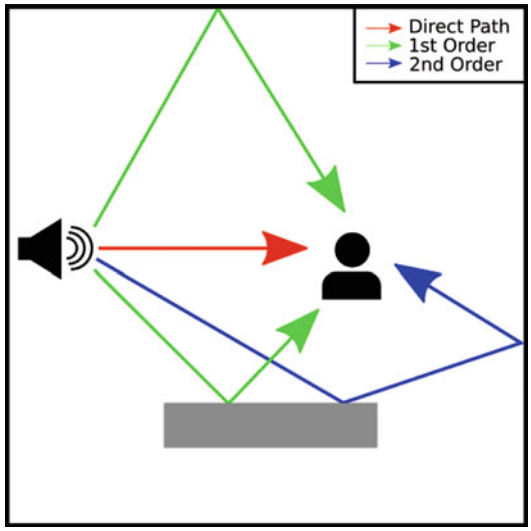
Sound design styles usually live on the spectrum of realistic versus abstract design. Realistic designs attempt to render diegetic sounds as realistically as possible, while abstract designs attempt to establish a sonic language to attach imaginative, emotional, or psychological meaning to specific sounds. Examples of diegetic sounds are the voice of characters in the story or sounds emanated by objects and their interactions in the scene. The acoustic character of the environment of a scene is implicitly defined by the rendition of the diegetic sounds given the geometry of space and objects in the scene. Examples of non-diegetic sounds are voiceovers, music, and abstract sound effects.

Sounds used in a game are often categorized in many different ways, and the designer has to make decisions about the spatialization of the sound and music based on a variety of parameters. When attending to the realistic aspects of the design, the spatialization of sounds should mimic physical effects of spatialization as much as possible. Spatialization of sounds need to happen in real-time in interactive games and some spatialization techniques may require considerable processing power. Therefore, a designer may choose to spatialize only some of the audio cues. Many aspects of spatialization techniques can be run in parallel and with the progress in computing technology, specifically in graphics processing units (GPU), spatialization of audio in more recent games is becoming more complete and lifelike. Generally, sound cues are separated in two distinct categories in regards to spatialization:

1. Sound Objects: these sounds are spatialized in real-time for the diffusion system used (speaker array, headphones, etc.) based on the position and head orientation of the player. Great emphasis is given to clearly depicting the proximity and direction of the objects in relation to the player, as well as to simulating the sonic effects of the objects' interaction with the acoustics of the virtual scene.
2. Ambient Sounds and Music: while these sounds may be spatialized, this step is often prepared in multichannel mixes (such as 5.1 mixes) which are in turn adapted to the diffusion system used. This approach requires less processing power for the spatialization process in real time.

Acoustics

Even though sounds propagate as waves in reality, for many applications including spatialization, and for understanding the interaction of a sound object with an acoustic environment, audio propagation is often modeled as emanation of sound rays. Some objects have specific frequency-dependent diffusion patterns (e.g., a speaking person emanates more sound towards the front than towards the back, especially more high-frequency sound). Figure 1 shows an example of different sound rays from a source arriving to a listener within an acoustic environment. In the interest of clarity, this figure is depicted in two dimensions; however, in reality and for synthesis of three-dimensional (3D) audio, one should consider this scenario in three dimensions. The direct ray arrives first and it is followed by low order reflections.



Spatial Audio and Sound Design in the Context of Games and Multimedia, Fig. 1 Examples of a direct ray, first and second order reflection paths

High-order reflections, which often fuse together as a diffused and decaying reverb sound, arrive last. Due to the Hass or "precedence" effect, the brain assumes that the source is located in the direction in which the first ray arrives to the listener (Haas 1972). Sound rays interact with boundaries and obstacles in the acoustic scene by reflection and diffraction. Sound rays are also filtered by the listener's body and ears, according to their anthropometric parameters. In order for a spatialization algorithm to create a realistic spatial impression, all of these physical effects must be simulated. The anthropometric parameters are discussed in the Binaural Processing section, and the interaction of the sources with the acoustic environment is discussed in the Acoustic Modeling section.

Diffusion Systems

Game audio can be diffused in various formats based on the capabilities of the game engine, computing hardware, and audio hardware. Designers need to consider both the technical and artistic aspects of these constraints. In some cases, the design may be flexible in supporting multiple diffusion formats.

Stereo

Stereo diffusion systems are by far the most prominent means of sound reproduction. These systems are designed for the playback of stereo audio signals, which consist of two channels referred to as *left* and *right* channels. In stereo diffusion, these channels are independently routed to loudspeakers placed to the left and right of a listener. The ideal speaker placement in this configuration is one in which the loudspeakers lie along a circle with the listener in the center, 30° off axis in either direction (Rumsey 2013). This configuration is typically accompanied by a subwoofer to accentuate the low frequencies of the audio; however, subwoofers are not necessary to achieve the stereo effect.

The stereo configuration allows for the perception of sound along a gradient of *left* to *right*. *Panning* refers to how present a sound is in either speaker with respect to its amplitude.

In stereo panning, often a *constant power* algorithm is used to make sure that, as a sound is panned from left to right, it maintains the same perceived volume and only changes in terms of its spatial location.

Surround Sound

Surround sound systems are diffusion systems which add additional speakers to a stereo configuration in order to create two or three-dimensional panning capabilities. The kinds of systems most commonly referred to by the term surround sound are 5.1 and 7.1 systems. In this notation, the first digit refers to the number of loudspeakers, and the second digit refers to the number of subwoofers. A standard 5.1 system includes two stereo speakers, a center channel, two "surround" speakers behind the listener, and a sub-woofer. A 7.1 system adds two "rear" speakers to a 5.1 system and shifts the surround speakers almost directly to the left and right of the listener. More recent systems add "top" speakers to create a sense of vertical displacement. These configurations are standard for movie and TV applications and can be adapted to both movie and home theaters. In academic settings, diffusion systems wherein speakers are evenly distributed along a circle, sphere, hemisphere, or polyhedron are commonplace and can accommodate three-dimensional panning.

Because of the variability between surround sound systems, surround sound audio is commonly rendered in either multiple formats or in a portable format that can be decoded to any given system. For example, the playback medium for a movie typically has stereo, 5.1, and 7.1 mixes to adapt to different home theaters. Spatialization techniques such as ambisonics, which will be discussed in detail later in this entry, store spatial audio information in a format which is independent of speaker placement and is thus highly adaptable to different configurations.

Headphones

Headphones are two-channel diffusion systems which sit on the ears of a listener and project sound directly into the tympanic cavity. Because headphones consist of two speakers, they are also well-suited to playback of stereo audio. Unlike loudspeaker systems, however, the acoustic qualities of a room are bypassed when listening to audio through headphones. This allows for the utilization of psychoacoustic effects to create a three-dimensional spatial image, which will be explored further in the discussion of binaural audio.

Audio Spatialization Techniques

Some spatialization techniques for speaker arrays such as wave field synthesis (Berkhout et al. 1993) and Moore's model (Moore 1983) control the amplitude and the delay of the signal over the multiple speakers. Other spatialization techniques such as Ambisonics (Gerzon 1975) and Vector Base Amplitude Panning (VBAP) (Pulkki 1997) control only the amplitude of the diffusion of audio signals for generation of spatial impressions. In the interest of brevity, the entry discusses only the Ambisonics technique, which is one the most prevalently used techniques, and the binaural rendering technique which is usually used for listening over headphones.

Ambisonics

Ambisonics recording technique (developed by Michael Gerzon in 1970s (Gerzon 1975)) has become prevalent in the field of professional and consumer three-dimensional audio. In its most basic format, this technique uses four directional microphones, positioned in a tetrahedron orientation, to record four audio signals, which are encoded to represent the three-dimensional sound pressure levels at the location of the microphone. This representation is in terms of the spherical harmonic components of the sound pressure field. Ambisonic decoding can be used to present the recorded media over a variety of audio diffusion system configurations including high fidelity loudspeaker configuration, and binaural reconstruction of the data for virtual and augmented reality equipment.

Figure 2 shows the orientation of the four microphones of a basic ambisonics microphone.

The signals from the four microphones are mixed as follows to obtain the B-format ambisonic signal:

$$W = LFD + RFU + LBU + RBD \quad (1)$$

$$X = LFD + RFU - LBU - RBD \quad (2)$$

$$Y = LFD - RFU + LBU - RBD \quad (3)$$

$$Z = -LFD + RFU + LBU - RBD \quad (4)$$

where LFD stands for left-front-down capsule, RFU for right-front-up capsule, LBU for left-

Spatial Audio and Sound Design in the Context of Games and Multimedia, Fig. 2 An ambisonic (soundfield) microphone with four capsules positioned in a tetrahedron configuration

back-up capsule, and *RBD* for right-back-down capsule.

A spatialized ambisonic signal from a mono source S could also be synthetically made with the following equations:

$$W = S * \sqrt{2} \tag{5}$$

$$X = S * cos(\theta) * cos(\phi) \tag{6}$$

$$Y = S * sin(\theta) * cos(\phi) \tag{7}$$

$$Z = S * sin(\phi) \tag{8}$$

where θ is the desired azimuth and ϕ the desired elevation for the spatial impression of the audio source S.

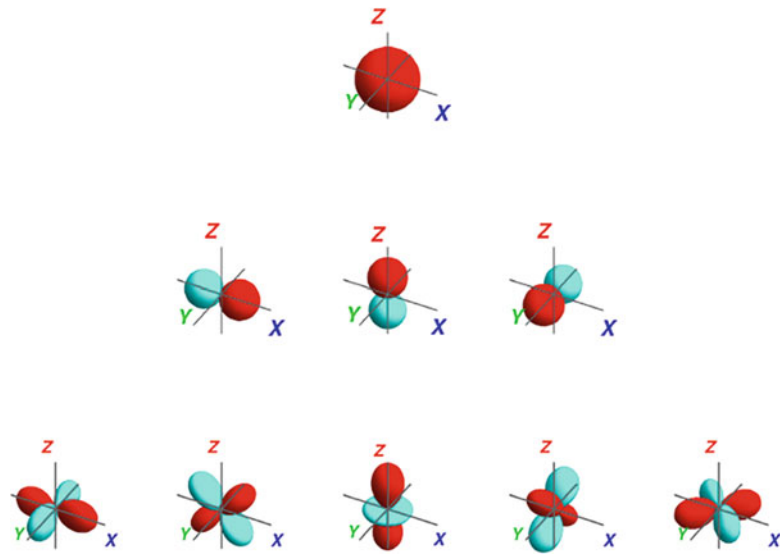
The W, X, Y, and Z in B-format represent the 0th and 1st order spherical harmonics shown in Fig. 3. Given a specific diffusion system, the decoding process works to decode the W, X, Y, and Z representations into signals appropriate for the chosen speaker orientation. Ambisonics technique provides a viable algorithm for diffusion of an Ambisonics recording in any speaker configuration. In other words, one will be able to present an ambisonic signal (recorded or synthesized) in many different venues with varying speaker configurations with little difficulty. One of the weaknesses of Ambisonics is that the spatial impression quickly deteriorates if one moves away from the sweet spot, but in the context of single-player games, this is not a shortcoming as long as the location of the player is always taken into consideration in the calculations.

Binaural

Binaural processing attempts to spatialize audio through headphones, or sometimes, through a set of stereo speakers. In everyday life, our brains interpret audio sources as pressure waves in the ear. The complex geometry of the pinna and ear canal act as an analog filter for the pressure waves before they reach the inner ear where the sound is transformed into neural information to our brain. Binaural processing attempts to characterize the physical (analog) filter given by the ear geometry into a digital filter.

Binaural Recording

The simplest form of binaural processing is to record audio sources using a torso-shaped mannequin with microphones placed inside silicone ears. The left and right ear microphones record a given



Spatial Audio and Sound Design in the Context of Games and Multimedia, Fig. 3 Spherical Harmonics of Order 0, 1, and 2

source as a stereo audio file which can then be played back to the listener through headphones. From the listener's perspective, the virtual source will be localized in the space where it was recorded.

Binaural Processing

One immediate downfall to binaural recording is the lack of listener input; wherever the original source was recorded relative to the mannequin is fixed and unchanging. It is possible to synthesize the binaural effect and account for the position and orientation of the listener in relation to virtual sources. Every position around the head produces a unique analog filter known as a Head Related Transfer Function (HRTF) for both the right and left ear (see Fig. 4).

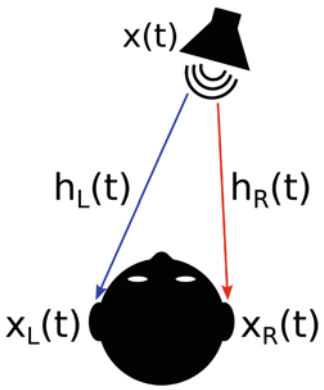
A virtual audio source can be spatialized using headphones if the audio signal is filtered using these position-dependent digital filters. The common method of implementing this spatialization technique is to record a set of impulse responses around the mannequin's head (called Head Related Impulse Response – HRIR). Each HRIR describes a digital filter given the location in space relative to the listener's head. Encoded in the digital filter are two major cues used for localization. The first cue is the *interaural level difference* (ILD) which characterizes the difference in sound level received by both ears. The other cue is the *interaural time difference* (ITD) which describes a time delay between each ear receiving the sound source. By performing convolution filtering of a mono audio source with both the left and right ear HRIR's, one can externalize and localize the audio source using headphones.

$$x_L(t) = \int x(t-\tau)h_L(\tau)d\tau \tag{9}$$

$$x_R(t) = \int x(t-\tau)h_R(\tau)d\tau \tag{10}$$

In this equation the signal that is to be spatialized is $x(t)$; the filters for the left ear and the right ear for the desired location in relation to the listener are represented by $h_L(t)$ and $h_R(t)$ respectively, and the signal that are diffused in the left and right ear of the listener are $x_L(t)$ and $x_R(t)$.

In binaural game audio, a specific HRIR is chosen and applied to the audio signal based on the position of a sound source in relation to player's position and head orientation. The player then hears the sound localized at the correct location and distance in the virtual world. It is also possible to produce a spatialization result with speakers by additionally implementing crosstalk cancellation between the speakers. While generic HRIR sets can produce fairly satisfactory results, each person possesses a unique set of HRIR. Modern binaural technologies include personalization of the applied HRIRs based on the player's various anthropometric data.



Spatial Audio and Sound Design in the Context of Games and Multimedia, Fig. 4 The source audio is filtered with an HRIR to produce the left and right ear versions of the signal

Acoustic Modeling

Acoustic modeling refers to the simulation of sound propagation in a virtual environment. While spatialization techniques can give the listener a sense of the angle and distance to the sound source, acoustic modeling allows the listener to hear the acoustical environment the sound is occurring in, by simulating how the sound interacts with room walls and other obstacles in the virtual environment. These obstacles cause two

key effects which must be simulated by acoustic modeling systems. First, sound reflects off obstacles, and low-order reflections are especially critical to the spatial impression (Bradley et al. 2003). Reflection simulation also includes simulation of sound absorption by the reflecting surface, which is often highly frequency-dependent. Second, sound diffracts around obstacles, which is readily apparent when sounds go around corners and behind obstacles (Svensson et al. 1999). Sound propagation can be accurately simulated with wavefield methods (Botteldooren 1995), but due to the enormous amount of computing power this requires, it is not presently a viable technique for real-time sound simulation in environments of nontrivial size. As a result, approximate models are used, with the quality dependent on the constraints of the application and the amount of available computing resources.

The most widely used acoustic modeling technique is reverberation, which simulates reflections and absorption in a generic enclosed room, usually using a convolution or a set of delay lines. Reverberation simulators typically only have a handful of parameters, such as the room size and the reflectivity of its walls, and as such can only give the listener a general sense of the size of the space. Nevertheless, reverberation has a very low computational cost and is even used in combination with more sophisticated techniques below to simulate very high-order reflections which are individually indistinguishable.

More complete acoustic modeling systems typically model sound propagation by rays. Approximating sound waves as rays is less straightforward than approximating electromagnetic waves (light) as rays in computer graphics, for two important reasons. First, the wavelength of sound is comparable to or even smaller than the size of obstacles, unlike in light simulation where the wavelength can be considered infinitely small in most cases. Second, information is usually encoded temporally on each sound "ray" – the original source sound signal – whereas an equivalent encoding in light rays is practically nonexistent in computer graphics. There are many approaches to modeling these wave effects with rays, and as a result, both the geometrical paths the rays traverse when reflecting and diffracting, as well as how this affects the resulting sound, differ substantially between acoustic modeling systems. These systems may also make different assumptions about the application, to trade off accuracy for computational complexity. For example, one common simplification is the assumption that the environment is a "shoebox" (axis-aligned rectangular prism), in which case diffraction does not play a role and reflection paths are easy to calculate. More sophisticated systems also exist which can handle scenes of arbitrary shape and complexity with moving obstacles.

Conclusion

Spatial audio can play an important role in game design. The directionality of audio can guide the listener's attention, and an ambient sound which is processed by a high-quality spatial algorithm can establish an effective sense of immersion for the player. High-quality acoustic modeling can greatly help the suspension of disbelief in establishing the virtual reality of the scene and interactive mechanisms within it. Designers need to consider and balance realism and detail against available processing power and player tracking sensors. Choosing artistic/narrative spatialization strategies and the optimal spatialization technique are important steps in the sound design process of a game.

Definition

Virtual environments (VEs) are inherently spatial and afford the use of natural spatial senses to navigate. However, VEs are not perfect in this regard, and there are important spatial perceptual issues to consider.

Introduction

Virtual environments (VEs) are inherently rich sources of spatial information, as they are multisensory simulations of a 3D space. This is particularly true when a VE is experienced immersively through motion tracking and head-mounted displays or similar systems. Depending on the hardware being used, a VE can provide stereoscopic depth cues through a 3D display, motion parallax from head tracking, 3D spatial audio, and even directional haptic or temperature cues from fans or heat-lamps that simulate a breeze or the warmth of sunlight. Most importantly, immersive VEs can afford the ability for users to move and navigate naturally, which engages body-based spatial senses. Spatial sensing of VEs does have some important limitations, however, and can be intentionally manipulated by VE developers to achieve particular effects.

Human Spatial Senses

Vision is the dominant source of spatial perception in humans. One can visually perceive distant landmarks to stay oriented or get re-oriented (e.g., the sun or a tall building) or use nearby landmarks as beacons for navigation (e.g., a door). Humans also readily pick up depth and 3D structure from visual cues and optic flow patterns (Gibson 1979). Such visual cues are easily conveyed through VEs in 3D renderings and real-time visual feedback from motion-tracked movement.

Audition is another common source of spatial information in VEs. Spatial auditory cues can indicate from what direction a sound is emanating and its proximity. Doppler Effects can indicate if it is approaching or receding. The way sound bounces and echoes throughout the environment conveys information about the 3D structure and its materials. Positional spatial audio is relatively common in the game engines used to drive VEs. Physically accurate simulation of sound propagation is computationally expensive, however, and often only approximated.

Proprioception, or body-based senses, produces spatial feedback from various body parts to perceive posture and movement. Limbs and joints can determine how far one has walked or turned, and whether or not one is crouching. The inner ear can detect gravity and acceleration to measure spatial "uprightness" and balance or a sudden change in movement. The tilt of one's ankles can indicate slope. These senses are often intertwined with *idiothetic* cues, or an internal measure of one's intentions (i.e., "I meant to walk 2 m forward. How close am I?"). In the real world these are near-constant sources of spatial information, but they can be lacking or inaccurate in a VE. Indeed, the absence of proprioception can make it easy to become disoriented or lost in a VE, which may necessitate aids such as a minimap or in-game compass.

The specific type of navigation interface plays a large role here. Navigation via natural walking in large-scale tracking spaces provides full access to these senses (e.g., Waller et al. 2007), while navigation via a gamepad ignores them altogether. Most navigation interfaces fall in between. Walking on a VE treadmill provides nearly natural walking motions in the legs, for example, but nonnatural accelerations to the inner ear. Walking-in-place navigation often relies on gesture-like approximations of walking. Teleportation techniques often allow full movement and proprioception in a small area, but with disconnected jumps between places. In some cases, semi-natural navigation can inhibit spatial perception and task performance (Marsh et al. 2013), so care must be taken in designing the VE interface.

Haptic feedback is less common in VEs, but can support spatial perception. Humans can use a sense of touch to navigate through dark environments, feeling their way along to a destination. In a VE, users can reach out for a wall or other object expected to be nearby. Its presence or absence can confirm or deny one's sense of being in a particular location.

Spatial Mis-perception in VEs

Perception of space in VEs is not always perfect. Despite the wealth of spatial cues, users tend to massively underestimate distance in VEs by as much as one half (Renner et al. 2013). Thus, a user asked to toss a ball into a basket 10 m away will often toss it around 5–7 m and be surprised when it misses. This effect has been documented in a wide variety of tasks, but there is some evidence that users can quickly accommodate to the VE with a few minutes of interaction (Richardson and Waller 2005).

Users also tend to mis-perceive inaccurate movement in VEs as being accurate as long it is reasonably close (e.g., Jaekl et al. 2005; Steinicke et al. 2009). This is due largely to the imprecision in human nonvisual senses. In the real world, one's body monitors if it has turned approximately 90° and small misalignments can be fixed visually. In a VE, errors in motion tracking or intentional manipulations by the VE developer may cause physical and virtual motion to be unequal. For example, a user might have to rotate 115° physically to achieve 90° virtual rotation. As long as the user feels like they have moved approximately the right amount in approximately

the right direction, visual cues will dominate and the VE is perceived as spatially stable and accurate.

This perceptual flexibility can be leveraged to influence navigation through a technique called Redirected Walking (Razzaque 2005). Redirected walking subtly manipulates a VE to induce users to turn away from tracking boundaries (and physical obstacles) and back into open space. This enhances user safety and increases the size of VE that can be explored in a smaller tracking area, without compromising normal spatial perception.

Other considerations of spatial perception in VE include the effects of limited field-of-view (FOV) and the visual conflict between accommodation and convergence. In the latter case, users' eyes receive conflicting information when focusing on an up-close screen that simulates a distal virtual object. In the former case, potentially useful information in one's peripheral vision is not rendered due to the limited FOV of a display (often around 100°) relative to natural vision (>180°). This can affect users' ability to detect if they have passed a nearby object, for example. Real-world objects leave one's periphery when they are passed, but an equivalent virtual object would disappear sooner.

Spatio-temporal Narrative Framework for Architecture in Video Games

Oğuz Orkun Doma
Architectural Design Computing, Istanbul Technical University, Istanbul, Turkey

Definitions

Our existence is temporal and spatial. Therefore the design of time and space is essential in narrative. As a form of design work in which the production and consumption cycles entirely take place in a digital medium, video games can also give us new perspectives on the experiential and representational relationships of the physical architecture, especially in an age when the borders between physical and virtual are blurring gradually. This study intends to get inspired from frame-works of narrative, space and time discussed in various types of media like cinema, affiliating with architecture. Then an original analytic framework for spatial and temporal experience in video game spaces will be delivered. The framework, complementing and re-contextualizing narrative and architectural theories of Genette, Lynch, Norberg-Schulz and Nitsche from a multidisciplinary perspective; can be used for the analysis of the architectural experience in the video games spatially, temporally, narratively and phenomenologically.

Introduction

Architecture can be thought as interactive environmental-spatial storytelling. In video games, the interactive architectural space creates an atmosphere to be experienced by the human being from inside the cyberspace via a *digital persona* or *avatar*. Everything player experiences during a video game directly addresses to player's senses; through the visual and auditory inputs, the video game space creates the ambiance, spatial mood, and visually transferred tactile feelings. As developing technologies, like haptics, allow more human senses to be involved in this process, the relationship of video games and architecture gets more and more concrete.

Video games cannot be reduced to some of its components or properties because of their complexity and diversity. Thus, to get a richer picture of video games, a multidisciplinary approach with a wide spectrum covering different yet interconnected perspectives is needed. Following the call for an interdisciplinary approach, experiences of spatiality, temporality, and narrative in video games will be discussed drawing on many other disciplines such as literature, architecture, and cinema. Firstly, how time and space are structured in the narrative in general will be examined. Through a careful reading of narrative theory of different forms, and approaches of various disciplines for the video game, studies will help to form an original analytical framework. After an overview of the foundational concepts, the framework will be proposed as

a framework to analyze video games and create level breakdowns in game design documents.

Methodology

There were three main concerns during the development of an analytic framework for video games: The first one is not to restrict the approach to an architectural-only perspective in video games, given that architecture is just one of the key components of a video game. Analysis of architectural experience in video game spaces is more than a reading and classification of architectural elements in the video games. The second concern is, as explained previously that video games cannot be reduced to their components, the analytical approach should be deductive rather than inductive. The third concern is to define the scope of the work carefully, given that one single theory cannot be applied to all video games. The video games discussed in this work are limited to computer and console games with 3D environments and 3D navigation.

The existing frameworks for analyzing the space and time in interactive narratives are mostly derived from other narrative forms like literature or cinema. Getting nurtured from these existing frameworks, this study aims to complement and recontextualize narrative and architectural theories of scholars, like Gerard Genette, Christian Norberg-Schulz, Kevin Lynch, and Michael Nitsche, and finally deliver an original framework which can be used in the analysis of 3D adventure games.

This study follows these four steps:

1. *Literature review* on video games and architecture, focusing on spatiality, temporality, and narrative, are examined.
2. *Criticizing the existing models* in order to create a combined and complementary original framework.
3. *Developing the analytical framework.*
4. *Development of a pictographic visualization*.

Each category and element of the framework is visualized with distinct and memorable pictograms, which serve as an interface for the analysis.

Space and Time Studies in Video Game Narratives

All the good tales always begin with "once upon a time, in a land so far away" or "A long time ago in a galaxy far, far away. . .." Such introductory stock phrases clearly reveal two defining elements of stories as time and space. As Bridgeman put it: "Temporal and spatial relationships are essential to our understanding of narratives and go beyond the specification of a date and a location" (Bridgeman 2007). It is not different in the digital narratives and video games. In narrative theory, the temporality was discussed more than the spatiality (Wei et al. 2010). If the stories are considered as sequences of fictional events, space is always required for events to take place in a progression timeline. Digital narratives being more immersive and interactive than the other forms of narratives, space becomes a fundamentally defining component of them. Murray explains the importance of space in digital narratives in her own words: "The new digital environments are characterized by their power to represent navigable space" (Murray 1997).

The space not only provides a place for the story events but also evokes images in the players' minds. The spaces may have symbolic meanings so that they can address the audience's past experience and start to become a storytelling device. Lynch states: "Nothing is experienced by itself, but always in relation to its surroundings, the sequence of events leading up to it, the memory of past experiences"(Lynch 1960). Jenkins also emphasizes the importance of space in video games, where he calls the video game designers as "narrative architects" (Jenkins 2004). Therefore, the spatiality and temporality should be considered as an integrated complex of space-time in narrative.

In this chapter, a literature review on the space and time studies in narratives are given with this spatiotemporal approach. Only a few of these studies are specific to digital narratives, but a careful adaptation of the works on other types of narratives would be useful in the scope of this article.

Space in Video Games

Spatial research of this article traces the discourse of Nitsche's 2008 work *Video Game Spaces*, in which he cites Norberg-Schulz: "The existential purpose of building (architecture) is therefore to make a site become a place, that is, to uncover the meanings potentially present in the given environment" (Norberg-Schulz 1980). Therefore creating a space is a call for precision, complementation, and symbolization of the natural spaces. An understanding as such requires a thorough reading and comprehension of the space, which leads into spatial recognition and cognitive mapping (Nitsche 2008).

Written by urban planner Kevin Lynch, *The Image of the City* is one of the most influential books on mental maps of observers' comprehension of the city, in which he extracted five common elements to shape individual cognitive maps (Lynch 1960):

1. *Path* – linear axes, such as streets, trails, and other channels
2. *Edge* – edges with directional qualities, such as buildings and walls
3. *District* – relatively large sections of the cities, identified by its characters
4. *Node* – focal points and intersections
5. *Landmark* – identified elements that also serve as reference points

A spatial structure can be identified with more than one of these elements according to the observer's position, or the defining elements can change in different scales. A city that consists of many *districts* can be recognized as a *node* in a larger map. In a similar manner, a bridge can be considered a *path* for those who walk on it, a *landmark* for those who view it from afar, and a *node* for those who take photos of the panorama from the bridge at the same time.

Cristopher Alexander proposes a model consisting of 253 patterns in *A Pattern Language* (Alexander et al. 1977). Lynch's cognitive elements are able to create various patterns in different combinations, whereas Alexander's classification is rather stricter. In this sense, Lynch's approach would provide a more flexible model for reading the video game spaces.

Frank Ching, a professor of architecture who is known for his works on architectural design and graphics, is more focused on the visual properties of the *form*, *space*, and *order* in architecture. Providing geometrical schemes for spatial relationship and spatial organization, Ching then introduces six ordering principles: *axis*, *symmetry*, *hierarchy*, *rhythm*, *datum*, and *transformation* (Ching 2007). Ching's principles and schemes are mostly focused on the formation and transformation of the spaces, while Lynch's elements are related to the mental images that these forms evoke in the observer's mind.

Nitsche proposes three spatial structure typologies and a model for content assembly:

1. *Tracks and Rails* – axes that have directional values and define a movement.
2. *Labyrinths and Mazes* – a complex track open to exploration with rather less visual cues.
3. *Arenas* – open structures with a surrounding enclosure.
4. *Driven by Space* – in space-driven model, narrative and possibilities of engagement are directly built into the way spatial structures are assembled.

Nitsche's model creates a typological classification for video game spaces. Although it regards the operational and functional values of spaces, elements like *nodes*, *districts*, and *landmarks* are still missing from this model.

Murray discusses how the emerging digital technologies are reshaping the stories and what possibilities they promise for the future of narrative. While Murray discusses *agency*, she approaches the digital narrative spaces as *digital labyrinths*. She states that "Electronic environments offer the pleasure of orienteering in two very different configurations, each of which carries its own narrative power: the solvable *maze* and the tangled *rhizome*" (Murray 1997). Murray's division of digital environments is rather operational than visual. However, their

operational structure would inevitably reveal itself in the visual language of the story spaces.

In narrative theory, spatiality is often underrated and treated as a static component of the story (Wei et al. 2010). Zoran's model stands out by distinguishing three different levels of the structuring of space for the written narratives, which belong to the reconstruction of the world and "they are always perceived together, one through the other":

1. *Topographical level* – "space as a static entity"
2. *Chronotopic level* – "the structure imposed on space by events and movements" (projections of the interior on the bottom of the cube)
3. *Textual level* – "the structure imposed on space by the fact that it is signified within the verbal text" (Zoran 1984)

The layered approach on spatiality of narratives interconnected with the temporality is a peculiar one in Zoran's model. However being created for written narratives in 1984, this model does not respond to any technologic and interactive aspects of video game spaces. Compared with Nitsche's study, it has been observed that both of them consider the story space as a reconstruction in the audience's mind and regard the topographical qualities of the spatial component of a story. However, Zoran's model focuses on the dynamic relationship of space and time better than Nitsche's model, but lacks the way Nitsche's model corresponds to the interactivity and the stories and actions embedded in the spatial entities.

After examining all these existing models, it has been decided that a model for analyzing and creating video game spaces should focus on (1) spatial structures, (2) functionality, (3) interaction, and (4) audiovisual inputs.

Time in Video Games

The most common approach on time in narrative theory is to divide the temporal modes of narrative into two: (1) *story time (ST)*, the timeline in which the acts and events of the story take place, and (2) *discourse time (DT)*, time that passes by when the story is being told. To analyze the syntax of narratives, Genette uses five main concepts; the first three concepts of Genette are closely related with the temporality of a narrative:

1. *Order* – the relation between the order of events happened in ST versus they are presented in the DT
2. *Duration* – the relation between the duration of events in DT versus ST
3. *Frequency* – the relation between how many times the events happened in DT versus represented in ST (Genette 1980)

David Herman develops the concept of *fuzzy temporality* (Wei et al. 2010) to expand Genette's study which is based on bivalent tempi (Herman 2002).

Jesper Juul also adapts the temporal duality to video game time: (1) *play time* and (2) *fictional time* (Juul 2011). Based on Juul's time frames, Hitchens presents a new model for game time:

1. *Playing Time* – the objective real-world chronological time experienced by a player during and between play sessions
2. *Game World Time* – chronological time within the game worlds
3. *Engine Time* – the objective chronological real-world time in which a game engine executes
4. *Game Progress Time* – an abstract measure of time tracking movement toward game completion and allowing events to be related in terms of happening order (Hitchens 2006)

These compared temporal models mainly rely on the temporal duality of real time and fictive time. The models that use multiple time frames seem consistent in themselves. However, one might argue if they could be considered universal for video game times, since their temporal classifications are "somewhat arbitrary" and "are not clearly defined" (Wei et al. 2010). Genette's concepts of *order*, *duration*, and *frequency* seem promising for a video game-specific

Spatio-temporal Narrative Framework for Architecture in Video Games, Table 1 The spatial characteristics of the framework

	Spatial characteristic		Function in gameplay	Function in narrative
Structures		Paths and trails	Affects motions and operations Defines the orientation in the space	Affects the story structure
		Zones and platforms		
		Rhizomes and networks		
Functionality		Spatial repulsion	Helps to create navigation patterns Shapes the operational relationships Encourages the exploration of the spaces	Defines the spatial effects Alters the emotional experience Attributes meanings to the spaces
		Spatial appeal		
		Spatial puzzle		
Interactivity		Character interaction	Creates new operational possibilities Intensifies the gameplay	Increases the level of agency Enriches the story universe Develops the stories
		Object interaction		
		Navigation	Shapes the orientation patterns of the levels Locates the gameplay elements in the game space Creates variety in gameplay	Defines the location of the story Increases the player's agency
		Objectives and challenges	Defines the gameplay rules and mechanics Creates variation in the gameplay Creates the navigation patterns	Helps to create the plot Increases the level of agency Alters the emotional experience Attributes meanings to the spaces
Sensuousness		Perspective and camera	Enables empathetic immersion Defines the player's field of vision Ensures the continuity of the space Guides the player through game space	Defines the agency level of the player Alters the emotional experience Enriches the story universe
		Color	Shows the hostility of the environment Guides the player through challenges Creates the navigation patterns	Sets the mood Alters the emotional experience Increases the level of reality Enriches the story universe Defines the chronologic context Increases the effect of synesthesia
		Materiality		
		Sound	Gives hints about the environment Shows the hostility of the environment Guides the player Keeps the player interested	Sets the mood Alters the emotional experience Increases the level of reality Enriches the story universe Verbal storytelling

Spatio-temporal Narrative Framework for Architecture in Video Games, Table 1 (continued)

	Spatial characteristic		Function in gameplay	Function in narrative
		Controls and body movement	Creates the link between the player and the in-game character Defines allowed motions and actions	Increases the level of agency Provides interactivity
		Interfaces	Sets the camera angles Helps to customize controls and configuration Provides essential gameplay information	Provides information

spatiotemporal model, but again, all the temporal frames need to be redefined and adapted for video games. Also, the aspect of *agency*, *flexible operational time*, and *selective order* of video game events needs to be added to the framework, which is going to be considered while developing the new framework.

Development of the Framework

The previous chapter remarks the importance of spatiotemporal approach and lists the existing models which could be utilized for a new analytical framework. The spatial and temporal characteristics of resulting combined analytical framework are listed in Tables 1 and 2.

Spatial Characteristics

The proposed framework for spatial characteristics is a rather hybrid and combined work which has a fourfold structure. Starting from the structure-only layer, each layer gets more interactive and perceptional elements involved than the layer before, creating a complete and evocative spatial environment when superposed in the end.

The four layers of the spatial characteristics are listed as:

1. *Structures* – the structural components of a video game.
2. *Functionality* – the functional meaning of a video game space reveals.
3. *Interactivity* – this layer is where the player's interaction with the space starts.
4. *Sensuousness* – in this layer, the players are inside the video game space via *avatars* or *personas*, and the reconstruction of the game world in their mind is created with the audio-visual sensory inputs of the spatial setting.

Temporal Characteristics

The proposed temporal model used in the framework is created considering the models explained in the previous chapter. Genette's ST and DT are redefined as (1) *playing time* and (2) *story time*. Considering the interactive dynamics and the flexible operational times of video games, two more spatial modes are added: (3) *game progress time*, the separate progression of game goals, and (4) *user created time (impromptu)*, the montage of story world events created by the player. Based on this narrative time frame, temporal characteristics of a video game are defined as (1) *sequence order*, (2) *narrative speed*, (3) *frequency*, and (4) *storytelling structure*. First three characteristics are adapted from three of Genette's concepts of narratology: *order*, *duration*, and *frequency* (Genette 1980), examining a previous adaptation of the theory to digital game storytelling made by Wei et al. (Wei et al. 2010). *Storytelling structures* are taken from Adams' classification of story structures (Adams 2010).

Pictographic Visualization

In the analytical framework, each spatial and temporal characteristic has three to six subcategories defining a typology or setting in the video games. These characteristics and subcategories are visualized with special pictograms designed for each title (Tables 1and 2). These patterns can lead to further analytical reading on which combinations can be considered more successful or which certain combinations enable what kind of impressions.

Spatio-temporal Narrative Framework for Architecture in Video Games, Table 2 The temporal characteristics of the framework

	Temporal characteristic		Function in gameplay	Function in narrative	Common forms in games
Sequence Order		Agent's choice	Increases player interaction	Increases the player's agency	Choosing between various objectives
		Flashback	Gameplay mechanic	Provides information Creates variety Expressive storytelling	Dialogue, cutscene, subtitles, screen caption, in-game texts, direct cut
		Flash-Forward	Gameplay mechanic	Provides information Creates variety Expresses storytelling	Dialogue, cutscene, subtitles, screen caption, direct cut
		Achrony	Provides side missions Alternative gameplay elements	Develops the story Increases agency	Choosing the order of side missions Skips
Narrative Speed		Scene	Increases the level of reality Immersive gameplay	Increases reality Immersive storytelling	Real-time mode
		Summary	Keeps the player interested	Succinct storytelling	Cutscene Voice-over Subtitle Direct cut
		Stretch	Gameplay mechanic	Creates variety	Cutscene Slow motion
		Ellipsis	Keeps the player interested	Succinct storytelling	Cutscene Voice-over Subtitle Direct cut
		Pause	Helps to customize settings Provides gameplay info Gives a break	Dramatic effect	Tutorial Cutscene Pause menu
Frequency		Singular	Keeps the player interested	Strong narrative	Event happens once
		Iterative	Keeps the player interested	Strong narrative	Recurring events shown once
		Repetitive	Practices a gameplay motif Progresses the player's skills	Creates variety in narrative	Repetition after illegal move or death Replaying the game

(continued)

Spatio-temporal Narrative Framework for Architecture in Video Games, Table 2 (continued)

	Temporal characteristic		Function in gameplay	Function in narrative	Common forms in games
		Multiple	Practices a gameplay motif Progresses the player's skills	Creates variety in narrative	Repeating gameplay motif
Storytelling		Linear	Increases the player interaction Provides alternative gameplays	Strong narrative Develops the story Creates variety in narrative Expressive storytelling Increases the player's agency	Single story with limited player effect on the plot
		Branching			Player choices develop the plot in different directions
		Foldback			Player's agency changes the direction of the story, but they fall back to inevitable key events
		Emergent			The player's agency can emerge unlimited storytelling possibilities

Conclusion

This article attempted to propose an analytical framework for the spatial and temporal characteristics in video games. The first question is: what architects can learn from the video games and how can the insights of this framework inspire them to shape the future of spatial environments with developing digital technologies? Another question is how this framework can be useful for video game designers? The framework was intended to be both an analysis and design tool. In the scope of this article, the framework was applied on single levels as case studies. If games are analyzed as a whole, and the pictographic pattern outputs of the analysis of different games are compared, the framework can illustrate repeating narrative and gameplay motifs visually. Such output can provide feedback for the designers for analyzing and designing video games.

Speedrunning

Definition

Speedrunning is a self-imposed method of playing a game to complete the story or campaign as fast as possible. The most popular types of speedrunning are any % (completing the storyline while undermining the intended way to play the game), 100% (completing all game content before completing the storyline), and low % (completing the game with the least amount of progression possible).

Introduction

Speedrunning has had a cult following with dedicated players and viewership since the popularization of the Internet in the 1990s. However, its popularity during the pandemic lock down has made headlines and mainstreamed speedrunning into its own genre, ushering in influencers, streamers, and pro players who would try it out for themselves.

To create and submit your own speedrun is very straightforward. Record your gameplay while also complying with the rules as to what kind of speedrun you are pursuing: any %, 100%, or low %, as well as record your time with a graphical UI tool. Moderators of the speedrun.com will analyze and confirm if your speedrun is eligible for the category that you have chosen.

Origin

The origin of speedrunning is debatable. Some suggest DOOM was the first speedrun, while others believe speedrun started with Ocarina of Time or Super Mario Bros. There is really no correct answer because speedrunning is still relatively new compared to other traditional activities such as speedreading and distance running in Olympics. However, Drag Race (developed by Kee Games in 1977) prompted Activision to create their own game Dragster in 1980 (Carter 2018). Dragster then released a promotional event that challenged players to complete the game in under 6 s (Carter 2018). Video game enthusiast Todd Rogers completed the game in a record time of 5.51 s. Nevertheless, in 2017 a

computer scientist claimed it was mathematically impossible to achieve Roger's time (Carter 2018). The report stated the fastest time possible: 5.57 s. While Dragster was the first videogame to ever implement speedrunning fundamentals, it was not until the release of the Internet did speedrunning became truly popular with DOOM and QUAKE.

Appeal of Speedrunning

The 1990s and 2000s are heralded to be the "Golden Age" of gaming. There were no microtransactions. Innovative and creative genres were created, and many great games known today have taken inspiration from the foundations established in the 1990s gaming scene. The success of DOOM and QUAKE took the speedrunning community by storm due to one new in-game feature: being able to record one's own gameplay (Brewster 2019). Online forums became a hotspot for sharing speedruns and thus new gameplay categories were created. Any %, 100%, and low % were established and they are still the most popular categories to play today. However, these three popular categories are not the only ways to speedrun games. Games that offer specific mechanics can create their own special speedruns. For example, complete the Super Mario Bros game as "little Mario" using no power ups or special items. For another example, Nuzlockes were created in 1995 to create a higher level of difficulty while playing the Pokémon game (Brewster 2019). The appeal of the added challenges was to prove that the challenges could be met, and it turned out to be a spectacle for the viewers when it turned into a competitive speedrun.

Since QUAKE and DOOM are very fast-paced First Person Shooters (FPS), these titles became two of the classics to speedrun. The added perspective of first person along with the skill, mechanics, game knowledge, and time dedicated captured the interest of many even the newcomers to speedrunning. The same concept can be applied to other games such as Ocarina of Time, Golden Eye, and Super Mario Bros. Speedrunning often introduces new methods of playing a game or teaches the players/viewers something they did not know about the game. The word of speedrunning would soon spread further as the community would branch into streaming.

Fundraising for Charities

The popularity of Twitch and YouTube have spread the word of speedrunning to its own communities and those willing to dive into it. Eventually a community in Texas would take the initiative to create their own brand on Twitch and YouTube. In 2008, TheSpeedGamers held their first speedrunning marathon playing through all the Zelda games, with all proceeds donated to St. Jude Children's Hospital for a total of $1090 (Carter 2018). Not only was this one of the first fundraising events hosted by local gaming enthusiasts, but it also inspired the creation of Games Done Quick (GDQ), a biannual speedrunning marathon that does fundraising for charities.

Ever since its conception in 2010, there have been news headlines with GDQ's brand detailing their support for victims of natural disasters, amount of donations to charities, number of donors, and comments from viewers. As of January 2022, GDQ had completed 146 games, consistently peaked at 100 k viewers, and amassed 3.5 million dollars for the Malala Fund on the platform Twitch (GDQ.stats 2022). Organizations sponsored GDQ and the event won the support of other speedrunning organizations worldwide such as the European Speedrunning Association (ESA). Speedrunning's popularity in the 2010s would only be overshadowed by recent life-changing events that unfolded on the world stage.

Lockdown and Conclusion

COVID-19 had forced lockdowns around the world. People had different experiences coping with the separation of family, work, and friends.

Traditional sports were canceled, commuting to work was no longer an option, and public outings or meetings with friends was severely limited or outright banned. With everyone locked inside their homes, many people surfed the Internet and played video games. During 2020 in the midst of lockdown, Google's trending search picked up "speedrunning" that gradually increased over time, peaked at 100 in December 2020, and finally subsided in March 2021 (Huebl 2021).

Speedrunning has become as popular as the word gaming. YouTube influencers and Twitch streamers share their experiences with the speedrun genre on their respective platforms. Speedrun.com, a website used to submit and archive new speedruns, grew by 128 K registered speedrunners in 6 months after lockdown (Huebl 2021). GDQ's proceeds increased 40% from 2018 to 2022, from $2.1 million to $3.5 million (GDQ.stats 2022).

Speedrunning's tempo has amassed over the years, adding more to its community akin to a snowball effect. Down to its tightknit mechanics and exhilarating gameplay, speedrunning is here to stay.

Any%; Clipping; Credit skipping; Lowest%; Random number generation manipulation; Routing; Sequence breaking

Definitions

100% = a speedrun category where speedrunners complete the game while getting every collectible or seeing every event. Some games have percent counters to signify when a game is 100% completed while other 100%s are chosen by community standards.

Any% = a speedrun category where speedrunners complete the game as fast as possible. Speedrunning = playing a video game as fast as possible by knowledge of specific routes needed to beat a video game.

Clipping = when two objects in a video game collide in unintended ways. Speedrunners can use clipping to pass through walls and barriers.

Credit skipping (also known as credit warping) = the act of using a glitch to start a video game's credits or ending sequence.

Lowest% = a speedrun category where speedrunners complete the game as fast as possible while doing the least amount of objectives. Some games have percent counters to signify when a game is at the lowest completion perfect while other game percentages are chosen by community standards.

Random number generation manipulation = referred to as RNG. The way a video game decides how random events occur. If a speedrunner has insight as to how a game is programmed, they can manipulate the game to their advantage.

Routing = the process of finding the fastest way to beat a video game.

Sequence breaking = performing actions in video games in ways unintended by the developers, typically earlier than usual.

Speedrunning

Speedrunning, in simplest terms, is completing a game, or parts of a game, as fast as possible. Players who speedrun are called speedrunners. Speedrunners record their runs to verify their time and to look for possible improvements. While the idea of beating video games quickly has existed since the advent of video games, the Internet has allowed players to create websites, forums, and communities dedicated to speedrunning. Nightmare Speed Demos is the earliest known website that hosted runs. It was created in 1996 in order to archive Quake speedruns.

Eventually, the site expanded to host speedruns of other games. Today, the largest website to catalog speedruns is Speedrun.com (Eva 2020).

With the advent of Youtube in 2005, speedrunning was able to grow in popularity as runs were more easily accessible to watch. Speedrunners also livestream their attempts as a way to record their runs while also adding an entertainment factor. Similarly, Twitch is another live streaming platform that has a large speedrun community. In 2011, Twitch was created as a separate category on Justin.tv but soon became more popular and the entire website was rebranded as Twitch in 2014. Speedrunners perform speedruns for their entertainment, to obtain a higher skill level for a game, or for a competitive aspect. Conventions are also another way the speedrunning community has grown in popularity. The earliest known speedrunning convention was Speedcon 2000 for the Quake community. The most widely known speedrunning convention today is Games Done Quick, where a weeklong marathon of speedruns are performed for charity (Gomez 2019).

Besides just playing at a faster pace than normal playthroughs of a game, speedrunners have extensive knowledge of what actions lead to the fastest way to completion. Routing is a term used to describe finding the best actions needed to complete the goal. Glitches are often used to skip cutscenes or sections of the game, allow for faster movement through areas, defeating enemies quickly, etc. Glitches that allow for players to skip directly to the game's credits are called credit skips. Glitches that allow the player to walk out of bounds are referred to as clipping. Perhaps one of the most famous speedrunning glitch is *Mario 64*'s Backwards Long Jump. Because *Mario 64* does not place a speed cap on backward momentum, players can perform long jumps backward on slopes to skip several parts of the game, such as the seemingly endless staircase, by gaining more momentum than intended by the developers. While not necessarily glitching, the act of sequence breaking is performing actions or events earlier than the game developers intended. In *Super Metroid,* the player can perform extremely precise jumps allowing Samus to reach new areas and collect several upgrades early. If a community knows enough about how a game is programmed, random number generation (RNG) manipulation can be used to ensure consistent results in areas where random events occur. For example, several games in the *Pokémon* franchise use RNG manipulation to ensure that their starting Pokémon has preferential stats.

Speedruns are separated in categories depending on the route. Any% is beating the game as fast as possible by any means. 100% is beating the game while getting all of the collectables, or anything else the community thinks is important. Lowest% is beating the game while doing the least amount of objectives. Glitchless, No Out of Bounds, and No Credits Warp are subcategories of the aforementioned categories that restrict using glitches, clipping, or credits warping, respectively. An example of a game that has a credits warp is *Pokemon Yellow*. In *Pokemon Yellow*, if the player resets the game while the game is attempting to save at a specific frame, the game will corrupt in such a way that it lets the player access the Pokemon menu option earlier than intended. With no Pokemon listed in the POKEMON menu, the player is able to scroll down below the normal sixth Pokemon slot. By

switching certain slots, the player can change the Item menu to behave similarly to the Pokemon menu by being able to scroll below the CANCEL button. From there, players will look for specific items in a list and manipulate them to switch the load zone from the player's house to the Hall of Fame, which will then start the credits sequence. With this trick, it is possible to beat *Yellow* in less than 1 min.

Individual Level runs refer to playing a certain level or part of a game, such as one track in *Mario Kart.* Speedrun communities make their own categories to fit what runs they find entertaining and/or competitive.

Spheres, balloons, balls; AABB, Aligned-axis bounding boxes; OBB, Oriented bounding boxes

Definition

According to Ericson (2005), a bounding volume is a computational and geometrical structure constructed for enveloping one or more objects. It is used to simplify the representation of the objects and is widely used for collision detection. The most common bounding volumes are spheres and boxes; however, there are others enveloping structures as ellipsoids, cylinders, and polygons, among others.

Introduction

Bounding volume, which is the minimum enclosing volume for an object, is widely used for computational geometry. It is called an external representation because there is another internal representation: the internal containing volume which is the maximum volume contained into the object. The purpose of using the internal representation is to accelerate the time required to detect collisions for a pair of colliding objects, whereas the external representation is mainly used to decrease the time required to reject collision for a pair of non-colliding objects. Arcila (2011) performed a comparison with collision detector of public domain.

Bounding volume has been widely used. It has been focused on collision detection (Xiao-Rong et al. 2009; Chang et al. 2010; Zhigang et al. 2010; Dinas and Bañón 2015; Rong et al. 2019), object detection (Sun et al. 2020; Rubino et al. 2015), collision queries (Gottschalk 2000), urban cellular automata (Xia et al. 2020), and improving techniques (Chang et al. 2010; Arcila 2011), among others.

The bounding volumes selected to represent objects, respectively, in two and three dimensions were circumferences and spheres, Axis-Aligned Bounding Rectangles (AABR) and Axis-Aligned Bounding Boxes (AABB), and Oriented Bounding Rectangles (OBR) and Oriented Bounding Boxes (OBB). Several works were developed using double representation approach for specific bounding volumes, Arcila (2011); Dinas and Bañón (2015) reported an extensive review.

Bounding Volume Hierarchies

Spheres and Boxes are popular in bounding volumes literature, and they are widely used for collision detection. Spheres have two advantages mainly: (i) Their representation is simple for constructing and testing; however, for elongated objects its representation is poor on accuracy, and (ii) they are invariant for translation and rotations, and it means the representation is calculated at the first time and they do not have to be updated after translation or rotations of the objects. The boxes are straightforward to calculate and they are invariant to translations. OBB is invariant to rotation, however, AABB representatiion changes after rotations.

Several authors have been working on combining two and more bounding volumes, for instance, Arcila (2011) included in their work a double representation of bounding volume hierarchy (for spheres, AABBs, and OBBs): an external and an internal representation. The external bounding volume has been extensively used; it determines quickly nonintersection between a pair of bounding volumes, which consequently, accelerate the broad phase process. Analogously, the internal bounding volumes label quickly a pair of objects as colliding objects and accelerate the collision detection process. Additional research reports the combination of two or more bounding volumes; for instance, Rubino et al. (2015) documented for a sequence of images, the combination of ellipsoids and AABB for three dimensional shapes using scenarios open and close. Dinas and Bañón (2015) documented a brief review of bounding volume hierarchies and applications on collision detection.

Bounding Volumes Requirements

Bounding volumes have been researched for several authors, some of them are being focused on the importance, the techniques, the applications, the cost for construction, the minimal requirements, and the evaluation cost, among others (Zhigang et al. 2010; Chang et al. 2010). Several authors have been focused on the computational cost, then they developed several strategies to decrease it, and reported comparisons and techniques for the most significant bounding volumes, whereas others' works have dealt with the requirements (Chang et al. 2010; Weller 2013). Following are some requirements for bounding volumes:

- ***Tight fitting to improve the accuracy of objects representation:*** The bounding volumes have to be as tight fitting for the object as possible; however, it is impossible to know a priori the topology of the objects. In real scenarios, objects have several shapes; hence, it is difficult to unify a bounding volume that adjusts all the different shapes. Hierarchies help to approximate different objects, but they need more space to be stored.
- ***Efficient construction:*** The construction of a bounding volume depends on the complexity of the structure; it is computationally expensive for tighter fitting volumes (Nguyen 2006).
- ***Efficient updating:*** Bounding volumes should be updated after rotation and translation transformations; however, it is not necessary for those that are invariant to both transformations.
- ***Efficient overlap tests:*** Tests with low-computational cost belong to straightforward structures for bounding volumes; spheres and boxes are included, for instance; however, they are not tighter fitting. In contrast, tighter fitting volumes are computationally expensive for both creating and testing (Zhigang et al. 2010; Chang et al. 2010).
- ***The low usage of memory:*** The memory usage depends on the complexity of the bounding volume. For spheres and boxes, the memory usage is lower than other complex structures.
- ***Suitable for creating the hierarchy:*** Hierarchies divide the object into small parts, and they are used to decrease the cost of overlapping tests and increase the accuracy of the representation in lower levels.

Bounding Volume Hierarchies Requirements

Each bounding volume fulfills some requirements but not all of them, even though they are essential. To select a bounding volume, it is required to

identify the application. Nevertheless, to guarantee efficiency, Nguyen (2006) defined a set of requirements to apply hierarchies on bounding volumes:

- ***Volume Approximation:*** The representation of children nodes must improve, in fit, the representation of their parent; it means, children should be tighter fitting than their parent.
- ***Enveloped Area:*** Children nodes must envelope the same part of the object enveloped by their parent.
- ***Automatic Construction:*** Human iteration must not be required for hierarchy construction.
- ***High Degree of Accuracy:*** The original model should fit as tightly as possible for the bounding volume hierarchy.

Bounding Volumes Performance

The Eq. 1 can be used to evaluating the performance of the bounding volume (Chang et al. 2010; Weller 2013; Dinas and Bañón 2015).

$$T = NuCu + NvCv; \tag{1}$$

The cost function (T) measures the intersection between a pair of bounding volumes. Nu and N_v are the number of bounding volumes checking and updates performed during the traversal process of the hierarchies and the number of overlapping tests performed over the bounding volumes, respectively. In contrast, C_u, and C_v are the average cost of performance change in the bounding volume caused by the motion and the average cost of an overlapping test performed between a pair of bounding volumes, respectively.

However, Eq. 1 was extended by Weller (2013) to include primitives; thus, the Eq. 2 separates bounding volumes and primitives.

$$T = NuCu + NvCv + NpCp; \tag{2}$$

Only for primitives, the number of overlapping tests is represented by N_p, whereas C_p represents the average cost of overlapping tests performed between primitives. In Eq. 3, C_o represents any additional time required in the process. Usually, it is user for transformation updates or coordinates updates for the objects. Analogously, C_o is defined as a onetime processing by Ericson (2005).

$$T = NuCu + NvCv + NpCp + Co \tag{3}$$

For instance, values N_u and C_u are not used in Eqs. 1 and 2 because circumferences and spheres, in two dimensions, and OBRs and OBBs, in three dimensions, are invariant to rotation. In contrast, the N_v value increases. The separation of bounding volumes and primitives in Eq. 3 reduces the overlapping test performed over bounding volumes (N_v) for Eq. 2, but increases, for primitives, the number of overlapping tests (N_p).

If the bounding volume hierarchy is not enough to detect a collision between the objects, it is required to compare the faces of the objects by a face-face test (Arcila 2011), which is computationally expensive and, consequently, unsuitable for detecting collisions in real-time applications. For that, Eq. 1 ignores the difference between bounding volumes and primitives, while Eqs. 2 and 3 establish the difference by using N_p and C_p for number and cost of primitives, respectively, and N_v and C_v for number and cost of bounding volumes. Following is a short description of Circumferences, Axis-Aligned Bounding Rectangle (AABR), and Oriented Bounding Rectangle (OBR).

Spheres

It encloses a convex polygon in the minimal circumference; it is called bounding circumference by James and Pai (2004). An advantage of these bounding volumes is the efficient calculation of distances and intersections between a pair of circumferences. Although circumferences are invariant to rotations and translation, for elongated objects, they are not a good bounding volume.

For bounding circumferences, the error is the empty space – it means the area of the circumference without including the area of the polygon.

Contrarily, for containing circumferences, the error is the polygonal area without including the containing circumference. An intersecting approach to the BD-Tree or Bounded Deformation Tree (James and Pai 2004) worked with deformable models of rigid bodies. The hierarchy was tighter-bound than others and can be updated quickly after deformation.

The circumferences representation is extended to the three dimensional spaces, then the spheres are used to enclose the objects. Moreover, Chang et al. (2010) combined OBB and spheres to take advantage of the better of each one. A set of works has been developed around collision detection using double representations (Arcila 2011; Dinas and Bañón 2015).

Axis-Aligned Bounding Box (AABB)

An AABR is a minimal enveloping rectangle that covers the object. Key benefits include: (i) The rectangle can be calculated easily; (ii) the translation does not change the rectangle because it is invariant to translations; and (iii) a pair of rectangles can be tested in a low-computational cost. Nevertheless, the rotation of the object affects the rectangle, then a change in the bounding rectangle is required after each rotation. Like circumferences, the error of AABR is the area of the rectangle uncovered by the polygon.

The extension of AABR changes Rectangles for Boxes. An study on the average time for AABB under several assumptions was performed by Weller et al. (2006), in order to increase the understanding of running time for the bounding volume. In contrast, the double representation proposed by Arcila (2011) included AABBs. The error of containing rectangle is the area of the polygon uncovered by the containing rectangle. Zhigang et al. (2010) proposed a hybrid technique, which combined and took advantage of both, OBB and AABB – the compact representation of OBB and the efficiency of AABB to perform the overlapping tests. Finally, Xiao-Rong et al. (2009) proposed an improved method, which decreases the storage space, and consequently, the time for detecting collision. A tree structure is the hierarchy used for bounding volumes.

Oriented Bounding Box (OBB)

In two dimensions, using the polygon orientation, the minimal rectangle to fill the polygon can be calculated. The invariance to translation and rotations is the most significant advantage of this representation. Accordingly, after moving and rotating the object, it is not required to compute a new OBR, but only focus the work on the collision test, which is computationally more expensive than the AABR collision test. Additionally, Rubino et al. (2015) documented the combination between ellipsoids with AABB.

OBB were used in three dimensions not only as bounding volumes but also as containing volumes by Arcila (2011). The calculation of the error for bounding and containing volumes is similar. The bounding volumes error is the area of the volume unoccupied by the polygons; contrarily, the area of the polygon unoccupied by the containing rectangle is the containing volume error. Gottschalk (2000) worked on the creation of both, a data structure and an algorithm exact and efficient for general polygonal models using hierarchies of sphere, AABB, and OBB. The hierarchy representation used was the tree. As a conclusion, Gottschalk (2000) demonstrated that, asymptotically and in special conditions, OBBs are faster than spheres and AABBs. Jian-Hong et al. (2008) and several studies for OBBs worked on increasing the fitting of the bounding volumes and improving the tests for overlapping. They used the Convex Hull1 of the object to improve the fitting of the OBB, whereas a prejudgment strategy was used to accelerate the overlapping tests before using a traditional method. A simplified model for collision detection using OBB was proposed by Rong et al. (2019).

Finally, they used double bounding volumes; Zhigang et al. (2010) and Xia et al. (2020) combined the better of AABBs and OBBs, whereas Chang et al. (2010) took advantage of OBB, for their compactness, and from spheres, for their simplicity.

Conclusion and Discussion

Bounding volumes are used to encapsulate the objects; they are compounded by an internal containing volume to accept collision quickly and an external bounding volume to reject intersections quickly. Circumferences, Axis-Aligned Bounding Rectangles (AABR), and Oriented Bounding Rectangles (OBR) were selected to represent the objects in two dimensions, whereas Spheres, Axis-Aligned Bounding Boxes (AABB), and Oriented Bounding Boxes (OBB) were selected to represent three-dimensional objects. Objects were divided into smaller parts to approximate their shape and to minimize the error caused by the representation; in contrast, the hierarchy is the used data structure to locate the object partition into a tree.

The selection of the bounding volume deals with two facts: on the one hand, the simplicity of the representation; it helps to reduce the time required to construct the volumes and the space required for storing them. On the other hand, a bounding volume is required that fits the object tightly; however, it can be a complex selection for objects with different shapes.

Star Wars Battlefront (2004), an Analysis

Randy Goodman[2] and Newton Lee[1,2]

Synonyms

First-person shooter; Video games

Definitions

First-person shooter (FPS)= a genre of games where the camera focuses on a gun (or other weapon) where the objective is to eliminate specific targets.

Introduction

Star Wars Battlefront, released in 2004, was developed by Pandemic Studios and published by LucasArts. The game was released on PC, Playstation 2, and Xbox. *Star Wars Battlefront* is the first game in the *Star Wars Battlefront* series, being followed by *Star Wars Battlefront 2*, and later being picked back up and remade by EA with the similar names *Star Wars Battlefront (2015)* and *Star Wars Battlefront 2 (2017)*. *Star Wars Battlefront* is a first and third person shooter that ran on the game engine Zero, and it had single-player and multiplayer capabilities. It has an ESRB rating of Teen. The game targeted anyone who enjoys large scale battles and anyone who is a fan of the Star Wars franchise as the game recreated battles on several key locations in the franchise.

Gameplay

Gameplay in *Star Wars Battlefront* is straightforward. Two teams are trying to do one of two things, either deplete the other teams reinforcement counter, which shows how many more soldiers they could call in, by killing enemies or capturing command points on the map. On every map, there are command points; they are certain zones that a team must capture by being inside the zone and then defend from the other team. On screen, there is a health bar, ammo, grenades, and a small mini map giving information on enemies and the positions of command points.

Star Wars Battlefront is fairly unique, and other than the fact that other games like Halo and Call of Duty are also first person shooters, there is not much similarity with other games. The exception to that is *Lord of the Rings: Conquest*, which was also created by Pandemic Studios, and is often criticized as being almost the exact same game. The only major differences are that Conquest is based around primarily melee combat while Battlefront is mostly ranged combat. The world of *Star Wars Battlefront* is made up from iconic planets from the Star Wars universe, such as Hoth, Geonosis, and Endor. Characters include the frontline troops for each faction, the CIS, Republic, Rebel Alliance, and the Empire, as

well as heros for the factions, such as Mace Windu and Count Dooku. *Star Wars Battlefront* only has three game modes. The first mode is Instant Action. It allows players to jump right into any battle you wanted. The other two modes are Galactic Conquest and the *Star Wars Battlefront* story mode, simply called Campaign.

Story

Weaknesses in Star Wars Battlefront come down to its lacking story mode, which left some players wanting more from its plot (Smith 2016). It was short and not put together in a story format, it is a mere series of battles. The public received Star Wars Battlefront (2004) well; it sold over four million copies by 2007 (Pham 2007). The biggest issue players had was a poorly done story mode, as it skipped around too much to form a coherent story and had players switching sides very often, causing the story mode to be confusing without other Star Wars media. Players praised the multiplayer modes and iconic scenes from the franchise. Ivan Sulic of IGN had praise for the games online mode, sound, and graphics while criticizing its single player for being too easy, incohesive, and having AI that "exhibits a type of intelligence roughly on par with the average rock's." They gave the game a score of 8.4/10 (Sulic 2004). Tom Bramwell of Eurogamer praised the game for showing the scale of what war would be like in the Star Wars universe while criticizing the optionality of battle objectives and win conditions (Bramwell 2004).

Microtransactions

The future games in the franchise changed direction along with a new publisher, Electronic Arts, or EA. EA decided to change several aspects of the game for its Battlefront and Battlefront 2, taking away a wide variety of maps for a smaller map pool, to which they only added on with DLC, and by removing several elements from the single player mode. EA also added microtransactions that undermined player progression, to the dismay of the playerbase (Scarpinito 2019). It is possible to achieve the same upgrades without purchasing microtransactions, but it takes a large amount of time and effort.

Artificial intelligence; Competition; Game AI; Real-Time Strategy games; RTS games; StarCraft

Definition

Real-time strategy (RTS) games is a subgenre of strategy games where players need to build an economy (gathering resources and building a base) and military power (training units and researching technologies) in order to defeat their opponents (destroying their army and base). Artificial intelligence (AI) problems related to RTS games deal with the behavior of an artificial player. Since 2010, many international competitions have been organized to match AIs, or bots, playing to the RTS game StarCraft. This entry presents a review of all major international competitions from 2010 until 2015 and details some competing StarCraft bots.

State-of-the-Art Bots for StarCraft

Thanks to the recent organization of international game AI competitions focused around the popular StarCraft game, several groups have been working on integrating many of the techniques developed for RTS game AI into complete "bots," capable of playing complete StarCraft games. In this entry we will overview some of the currently available top bots and their results of recent competitions.

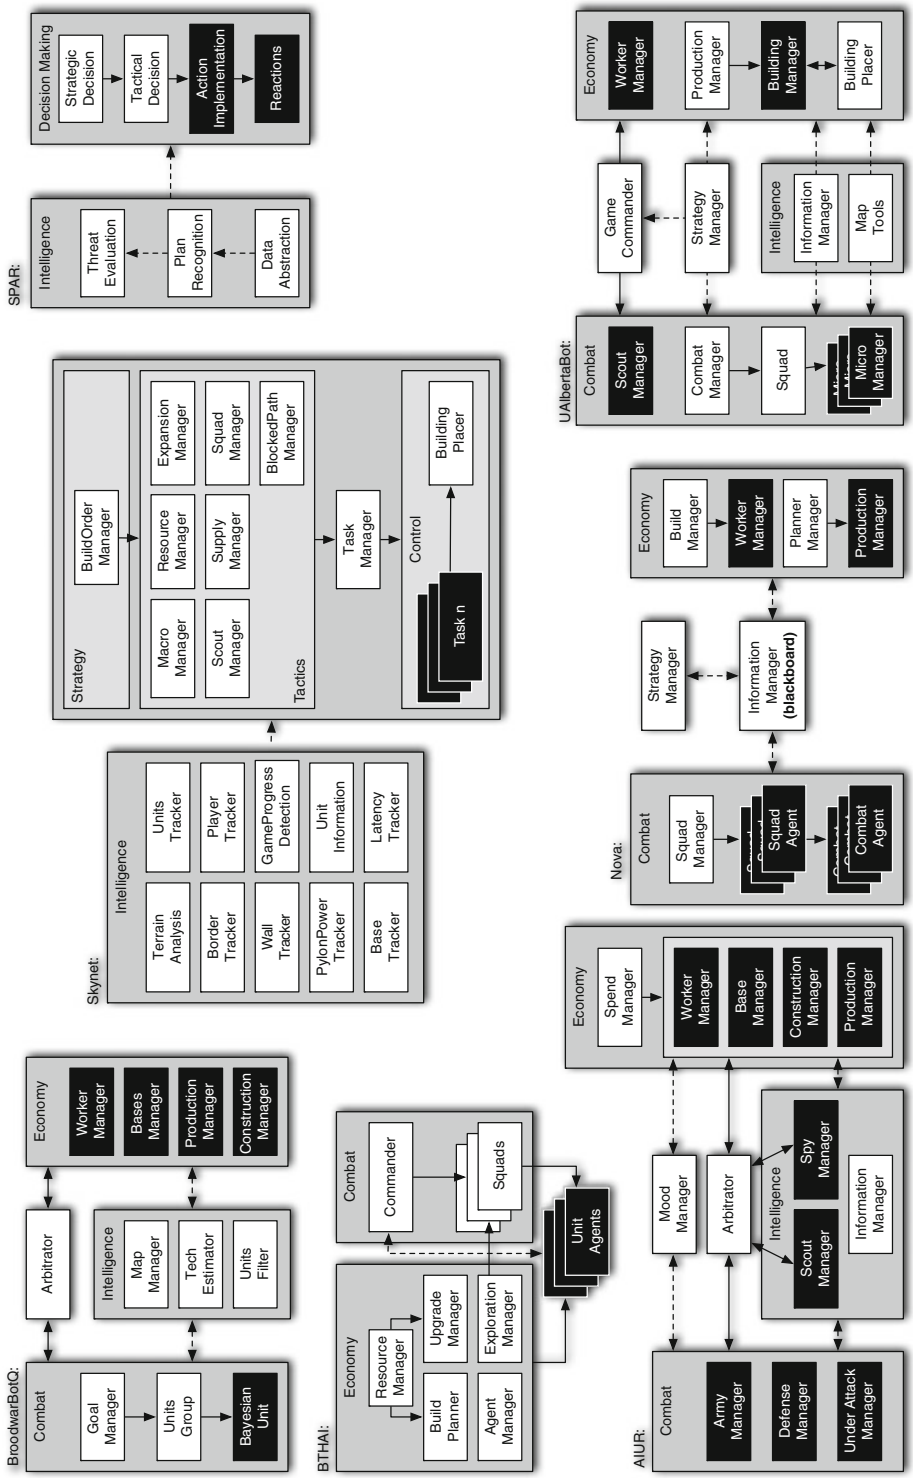
Playing an RTS game involves dealing with a wide variety of problems, ranging from micro-management problems such as unit control to macro-management problems such as resource allocation. A few approaches, like CAT (Aha et al. 2005), Darmok (Ontañón et al. 2010), or ALisp (Marthi et al. 2005), try to deal with the problem in a monolithic manner, by using a single AI technique. However, none of those systems aim at achieving near-human performance. In order to achieve human-level performance, RTS AI designers use a lot of domain knowledge in order to divide the task of playing the game into a collection of subproblems, which can be dealt with using individual AI techniques.

Figure 1 shows some representative examples of the architectures used by different bots in the AIIDE and CIG StarCraft AI competitions (see section "Synonyms"): BroodwarBotQ (Synnaeve et al. 2011), Nova (Uriarte and Ontañón 2012), UAlbertaBot (Churchill and Buro 2011), Skynet, SPAR, AIUR, and BTHAI (Hagelbäck 2012). Each box represents an individual module with a clearly defined task (only modules with a black background can send actions directly to StarCraft). Dashed arrows represent data flow, and solid arrows represent control (when a module can command another module to perform some task). For example, we can see how SPAR is divided in two sets of modules: *intelligence* and *decision-making*. Intelligence in SPAR has three modules dedicated to analyze the current situation of the game. Decision-making in SPAR is done through four hierarchically organized modules, with the higher-level module (*strategic decision*) issuing commands to the next module (*tactical decision*), which sends commands to the next module (*action implementation*), and so on. Only the two lower-level modules can send actions directly to StarCraft.

On the other hand, bots such as Nova or BroodwarBotQ (BBQ) only use a hierarchical organization for *combat* (controlling the attack units), but use a decentralized organization for the rest of the bot. In Nova and BBQ, there is a collection of modules that control different aspects of the game (workers, production, construction, etc.). These modules can all send actions directly to StarCraft. In Nova those modules coordinate mostly through writing data in a shared blackboard, and in BBQ they coordinate only when they have to use a shared resource (unit) by means of an arbitrator: a bidding market and broker for settling unit control; military and civilian groups/task forces bid for units proportionally to their usefulness and the task importance.

By analyzing the structure of these bots, we can see that there are two main tools being used in these integration architectures:

– *Abstraction*: complex tasks can be formulated at different levels of abstraction. For example, playing an RTS game can be seen as issuing individual low-level actions to each of the units in the game, or at a higher level, it can be seen as deploying a specific strategy (e.g., a "BBS



StarCraft Bots and Competitions, Fig. 1 Architecture of seven StarCraft bots obtained by analyzing their source code. Modules with black background sent commands directly to StarCraft, dashed arrows represent data flow, and solid arrows represent control

strategy" or a "Reaver Drop" strategy). Some bots reason at multiple levels of abstraction at the same time, making the task of playing StarCraft simpler. Assuming that each module in the architecture of a bot has a goal and determines some actions to achieve that goal, the actions determined by higher-level modules are considered as the goals of the lower-level modules. In this way, each module can focus on reasoning at only one level of abstraction, thus, making the problem easier.
- *Divide-and-conquer*: playing a complex RTS, such as StarCraft, requires performing many conceptually different tasks, such as gathering resources, attacking, placing buildings, etc. Assuming each of these tasks can be performed relatively independently and without interference, we can have one module focusing on each of the tasks independently, thus making the problem easier.

If we imagine the different tasks to perform in a complex RTS game in a two-dimensional plane, where the vertical axis represents abstraction and the horizontal axis represents the different aspects of the game (combat, resource gathering, etc.), abstraction can be seen as dividing the space with horizontal lines, whereas divide-and-conquer divides the space using vertical lines.

Different bots use different combinations of these two tools. Looking back at Fig. 1, we can see the following use of abstraction and divide-in-conquer in the bots:

- BroodwarBotQ (http://github.com/SnippyHolloW/BroodwarBotQ): uses abstraction for *combat* and divide-and-conquer for *economy* and *intelligence gathering*. To avoid conflicts between modules (since the individual tasks of each of the modules are not completely independent), BBQ uses an arbitrator.
- Nova http://nova.wolfwork.com/: is similar in design as BroodwarBotQ and uses abstraction for *combat* and divide-and-conquer for *economy*. The differences are that Nova does not have an arbitrator to resolve conflicts, but has a higher-level module (*strategy manager*), which posts information to the blackboard that the rest of modules follow (thus, making use of abstraction).
- UAlbertaBot (http://github.com/davechurchill/ualbertabot/): also uses abstraction in *combat* like the previous two bots. But it also uses it in *economy*: as can be seen, the production manager sends commands to the building manager, who is in charge of producing the buildings. This bot also uses divide-and-conquer, and tasks like scouting and resource gathering are managed by separate, independent modules.
- Skynet (http://code.google.com/p/skynetbot/): makes extensive use of both abstraction and divide-and-conquer. We can see a high-level module that issues commands to a series of tactic modules. The collection of tactic modules queue *tasks* (that are analogous to the abstract actions used in SPAR). Each different task has a specific low-level module that knows how to execute it. Thus, Skynet uses a three-layered abstraction hierarchy and uses divide-and-conquer in all levels except the highest.
- SPAR (http://www.planiart.usherbrooke.ca/projects/spar/): only uses abstraction. Its high-level module determines the strategy to use, and the tactical decision module divides it into a collection of *abstract actions*, which are executed by the lower-level modules.
- AIUR (https://github.com/AIUR-group/AIUR): is mainly divide-and-conquer oriented, with a slight abstraction on *economy* due to a Spend Manager deciding how to spend and share resources among Base, Production, and Construction Managers. At the beginning of a game, the Mood Manager initializes a "mood" which will influence both tactics and strategy. *Combat* is divided into three independent managers: the *Defense Manager*, controlling military units when there is nothing special; the *Under Attack Manager*, activated when the opponent is attacking our bases; and the *Army Manager*, taking control of units when it is time to attack, following a timing given by the current mood. This bot does not manage however any kind of reactive controls so far.

– BTHAI (https://github.com/jhagelback/oppri mobot): uses a two-tier abstraction hierarchy, where a collection of high-level modules command a collection of lower-level agents in charge of each of the units. At the high level, BTHAI uses divide-and-conquer, having multiple high-level modules issuing commands to the lower-level units.

Additionally, except for BTHAI, all other agents use divide-and-conquer at a higher-level bot design and divide all the modules into two or three categories: *intelligence gathering* and *decision-making* (sometimes divided into *combat* and *economy*).

Some bots using divide-and-conquer assume that each of the modules can act independently and that their actions can be executed without interference. BBQ, UAlbertaBot, and AIUR, however, use an arbitrator (*Game Commander* in UAlbertaBot) that makes sure that modules do not send contradictory orders to the same unit. However, very little bots handle the problem of how to coordinate resource usage among modules, for instance, BTHAI uses a first-come-first-serve policy for spending resources, and the first module that requests resources is the one that gets them. Nova and Skynet are exceptions and implement some rudimentary prioritization based on the high-level strategy. Following available resources and timing, AIUR's *Spend Manager* orders Base, Production, and Construction Managers what they have to build/produce. It also orders to start tech research and upgrades. The idea here is not to let the different managers allocate the resources they want, but to do the opposite, that is, finding how the AI can spend the available money.

One interesting aspect of the seven bots described above is that, while all of them (except AIUR) are reactive at the lower level (reactive control), most, if not all, of them are scripted at the highest level of abstraction. BTHAI reads build and squad formations from a predefined script, Nova's *Strategy Manager* is a predefined finite-state machine, BBQ's construction manager reads the build order from a predefined script, and Skynet's *Build Order Manager* is basically a predefined script. Such scripts describe the strategy that the bots will use; however, such strategy is always fixed. One could see this prescripting as if each bot defined a "high-level programming language" to describe StarCraft strategies, and the bots themselves are just interpreters of such strategy. Compared to current approaches for Chess or Go, this scripting seems rigid and inflexible, but responds to the much higher complexity of the StarCraft game. An interesting exception to that is UAlbertaBot, which uses a search algorithm in the *Production Manager* to find near-optimal build orders. Another interesting case is AIUR, which uses a *Mood Manager* to randomly pick a mood among six (cheese, rush, aggressive, defensive, macro, fast expand), which will influence the build order, strategy, and tactics.

In conclusion, we can see that there are two basic tools that can be used in an integration architecture: abstraction and divide-and-conquer, which are widely used by the existing StarCraft bots. For space reasons, we do not include an exhaustive comparison of the architectures of all the participating bots. Some more bots than the ones described here have been documented by their authors, such as SCAIL (Young et al. 2012b) or QUORUM (Young et al. 2012a). Let us now focus on their performance in recent competitions.

Recent StarCraft AI Competitions

This section reviews the results of three recent international competitions on AI for StarCraft. These competitions have been possible thanks to the existence of the Brood War Application Programming Interface (BWAPI) (https://github.com/bwapi/bwapi), which enables replacing the human player interface with C++ code. The following subsections summarize the results of StarCraft AI competitions colocated with two scientific conferences – AIIDE (Artificial Intelligence for Interactive Digital Entertainment) and CIG (Computational Intelligence in Games) – and one stand-alone competition called SSCAIT (Student StarCraft AI Tournament), during the past years. Since 2011, the CIG and AIIDE competitions have typically been held in August/

September in each year, as the conferences are scheduled quite close to each other, and SSCAIT has been held in December/January. As a consequence of this, AIIDE and CIG competitions share a big portion of the entrants.

AIIDE

AIIDE 2010. Started in 2010, the AIIDE StarCraft AI Competition (http://www.StarCraftAICompetition.com) is the most well-known and longest running StarCraft AI Competition in the world. Each year, AI bots are submitted by competitors to do battle within the retail version of StarCraft: Brood War, with prizes supplied by Blizzard Entertainment.

The first competition in 2010 was organized and run by Ben Weber in the Expressive Intelligence Studio at the University of California, Santa Cruz (http://eis.ucsc.edu/StarCraftAICompetition). Twenty-six total submissions were received from around the world. As this was the first year of the competition and little infrastructure had been created, each game of the tournament was run manually on two laptop computers and monitored by hand to record the results. Also, no persistent data was kept for bots to learn about opponents between matches.

The 2010 competition had four different tournament categories in which to compete. Tournament 1 was a flat-terrain unit micromanagement battle consisting of four separate unit composition games. Of the six competitors, FreSCBot won the competition with Sherbrooke coming in second place. Tournament 2 was another micro-focused game with nontrivial terrain. Two competitors submitted for this category, with FreSCBot once again coming in first by beating Sherbrooke.

Tournament 3 was a tech-limited StarCraft game on a single known map with no fog-of-war enforced. Players were only allowed to choose the Protoss race, with no late-game units allowed. Eight bots faced off in this double-elimination tournament with MimicBot taking first place over Botnik in the final. As this was a perfect information variant of StarCraft, MimicBot adopted a strategy of "mimic its opponent's build order, gaining an economic advantage whenever possible" which worked quite well.

Tournament 4 was the complete game of *StarCraft: Brood War* with fog-of-war enforced. The tournament was run with a random pairing double-elimination format with each match being best of five games. Competitors could play as any of the three races, with the only limitations in gameplay being those that were considered "cheating" in the StarCraft community. A map pool of five well-known professional maps were announced to competitors in advance, with a random map being chosen for each game.

Results are shown in Table 1. The team that won was Overmind (http://overmind.cs.berkeley.edu), from the University of California, Berkeley. Using the Zerg race, their strategy was to defend early aggression with zergling units while amassing mutalisk units, which they used to contain and eventually defeat their opponents. The mutalisk is a very fast and agile flying unit which is able to attack while moving with no drawback, which makes them quite a powerful unit when controlled by a computer. Overmind used a potential field-based micromanagement system to guide their mutalisks, which led them to victory. Krasi0 came in second place with a standard defensive Terran opening strategy that transitioned into "mech" play in the late game.

AIIDE 2011. In 2011 the University of Alberta hosted the competition, with organization by Michael Buro and David Churchill (https://skatgame.net/mburo/sc2011/). Due to a lack of entrants in tournament categories 1–3 in the 2010 competition, it was decided that only the full game category would be played in the 2011 competition, with 13 entrants. Another important change in the 2011 competition was the introduction of automated tournament managing software running StarCraft games simultaneously on 20 computers, allowing a total of 2340 games to

StarCraft Bots and Competitions, Table 1 Ranking of the three best bots of the AIIDE 2010 competition

Rank	Bot
1	Overmind
2	Krasi0
3	Chronos

be played in the 5 days that the tournament ran. This increase in games played also allowed the tournament to switch to a round-robin format, eliminating the "luck" factor of the pairings inherent in bracket-style tournaments. The bot that achieved the highest win percentage over the course of the competition would be determined the winner. Also, the competition became open-source, in an effort to prevent possible cheating and to promote healthy competition in future tournaments by giving newcomers and easier entry point by basing their design off of previous bots. All maps used by the competition were known long time by advance, so participants can test their bot on them. These ten maps remain the same for all AIIDE competition, from 2011 until the last one at the time this chapter has been written in 2015. Maps are *(2) Benzene*, *(2) Destination*, *(2) HeartbreakRidge*, *(3) Aztec*, *(3) TauCross*, *(4) Andromeda*, *(4) CircuitBreaker*, *(4) EmpireoftheSun*, *(4) Fortress*, and *(4) Python*. The number between the parentheses is the number of possible start points.

In the end, Skynet won the competition with its solid Protoss play (results are summarized in Table 2). The bot executed one of a small set of strategies randomly at the start of the match based on the map and the race of the opponent. Skynet would then amass a medium- to large-sized army and expand before moving out to attack. Good use of Dragoon (powerful ranged ground unit with clumsy movement) range and kiting micromanagement allowed it to hold off the early aggression of other bots such as UAlbertaBot, which came in second.

UAlbertaBot used an early Zealot rush strategy to take advantage of the power of early-game Protoss units. It would send out the first Zealots that were made and immediately attack the enemy base, using a unit counting heuristic to determine whether or retreat or keep pushing. Of note is that UAlbertaBot used an online planning algorithm to construct all of its economic build orders (Churchill and Buro 2011), as no hard-coded build orders were used.

StarCraft Bots and Competitions, Table 2 Results of the five best bots of the AIIDE 2011 competition

Rank	Bot	Win %
1	Skynet	88.9
2	UAlbertaBot	79.4
3	AIUR	70.3
4	ItayUndermind	65.8
5	EISBot	60.6

AIUR also chose Protoss, with a strategy that was in between Skynet and UAlbertaBot in terms of attack timings. At that time, AIUR chose one mood among five (leading to slightly different strategies and tactics) at the beginning of a game and kept it until the end. These five moods were (1) Rush: the bot tries early attacks and has good probabilities to send the two or three first Zealots (basic contact attack ground unit) to harass the opponent. (2) Aggressive: it has less chance to perform harasses with the first Zealots, and the first attack is usually a bit delayed with regard to the Rush mood. (3) Macro: the AI do not try any early attacks and focus a bit more on its economy before attacking. (4) Defense: AIUR "turtles" and wait to have a consequent army before running an attack. (5) Fast expand: the first building constructed it a base expansion, for a very economy-oriented game. Notice that build orders are not fully hard-coded since they can be altered by AIUR's Spend Manager.

Of note in these results was that a rock-paper-scissors effect happened among the top three finishers. Of the 30 rounds, Skynet beat UAlbertaBot 26 times, UAlbertaBot beat AIUR 29 times, and AIUR beat Skynet 19 times. Another notable result is that Overmind did not choose to compete despite winning the 2010 competition. After the competition, many bot programmers (including the Overmind team) realized that their 2010 strategy was quite easily defeated by early-game rushing strategies, and so they submitted a Terran bot instead, called Undermind, which finished in seventh.

AIIDE 2012. The University of Alberta also hosted the 2012 competition, with the major difference from the 2011 competition being the addition of file reading and writing for learning. Bots could now write information to disk during a match and then read the information during other matches, allowing them to adjust strategies based

StarCraft Bots and Competitions, Table 3 Results of the five best bots of the AIIDE 2012 competition

Rank	Bot	Win %
1	Skynet	84.4
2	AIUR	72.2
3	UAlbertaBot	68.6
4	BroodwarBotQ	59.1
5	AdjutantBot	52.8

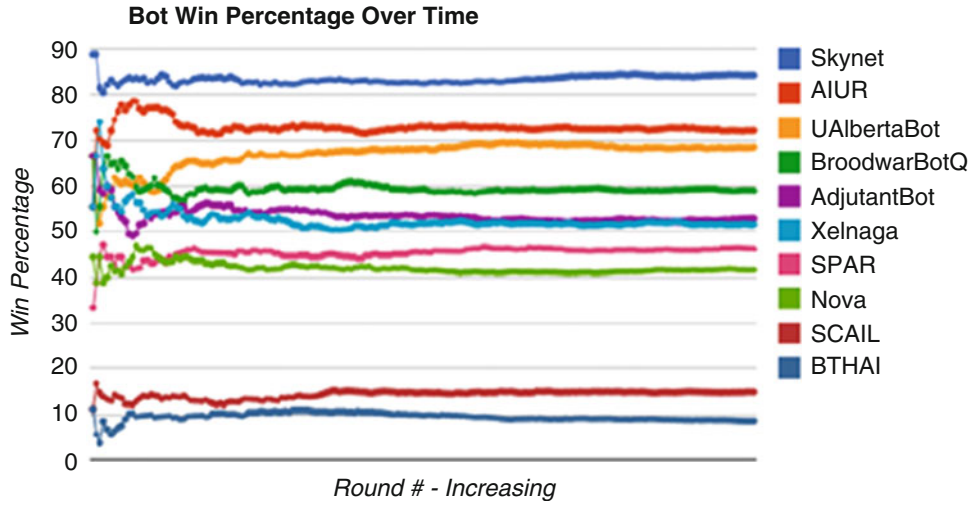
on previous results. Six of the ten entrants used this feature to aid in strategy selection, including the top four finishers. More improvements to the tournament environment also meant that a total of 8279 games could now be played in the same time period. Results are shown in Table 3.

Skynet once again won the competition with its solid Protoss build orders and good Dragoon kiting. AIUR and UAlbertaBot switched positions from the previous year to come second and third, respectively. Both AIUR and UAlbertaBot used data stored from the results of previous games to select a strategy for future matches. UAlbertaBot did this using the UCB (Auer et al. 2002) algorithm, while AIUR used a uniform distribution to choose its mood before altering this distribution after some games against the same opponent to favor efficient strategies, achieving similar results than UAlbertaBot. Notice that, compared to AIIDE 2011, AIUR proposes a new mood, *Cheese*, implementing a Photon Cannon rush strategy in order to surprise the opponent and to finish the game as soon as possible. The effect of this strategy selection process can be seen Fig. 2 which shows bot win percentages over time. While the earlier rounds of the tournament fluctuated wildly in results, eventually the results converged to their final values. One of the main reasons for this is due to the bots learning which strategies to use as the tournament progressed.

AIIDE 2013. A total of eight bots competed in the 2013 AIIDE competition with many of the same names from the 2012 competition, and some key updates were made to existing bots for 2013 which shook up the results from the previous years. A total of 5597 games were played during the 5-day tournament. UAlbertaBot took first place with a dominant 84.49 % win rate, with Skynet in second with 72.77 % (Table 4). The major addition to UAlbertaBot was a combat simulation package called SparCraft. UAlbertaBot was reengineered so that it now always attacked from the first combat unit created, using the SparCraft system to simulate whether or not the bot could fight against known enemy units, retreating automatically if it thought it could not. This addition, combined with some additional bug fixes, led to the victory. Skynet and AIUR both implemented strategy learning in 2013, which is evident from three in which both Skynet and AIUR's win percentage over time climbs dramatically from the first few rounds of the tournament to the later rounds. Ximp unfortunately crashed all games on the Fortress map and lost 10 % of its games for free as a result, which meant it could have possibly came in second place if not for all those crashes (Fig. 3).

AIIDE 2014. The 2014 AIIDE competition saw 18 total entrants, over double the number from the 2013 competition. This dramatic increase in numbers was partially because of a large advertising effort by competition organizers, combined with the inclusion of all the 2013 competition entrants (if they had not resubmitted new versions). UAlbertaBot and Skynet who finished first and second the year before were not updated in 2014 and so their previous versions were resubmitted. Along with the larger registration numbers came a lot of new Terran bots, a welcome change from the Protoss-dominated fields of previous years. The tournament managing software also underwent some major updates in 2014, allowing for faster game scheduling and the easy pausing and resuming of tournaments, resulting in 10251 total games being played, which was almost double the amount of 5579 from the previous year.

The results of the 2014 competition were dramatically different from previous years (Table 5). Since 2011 the top three bots in the AIIDE competition had been some permutation of Skynet, UAlbertaBot, and AIUR, and in 2014 the top 3 finishers were all completely different. In first place was ICEBot with a win rate of 85.85 %, which had a complete overhaul in terms of strategy and tactics from the previous year. ICEBot



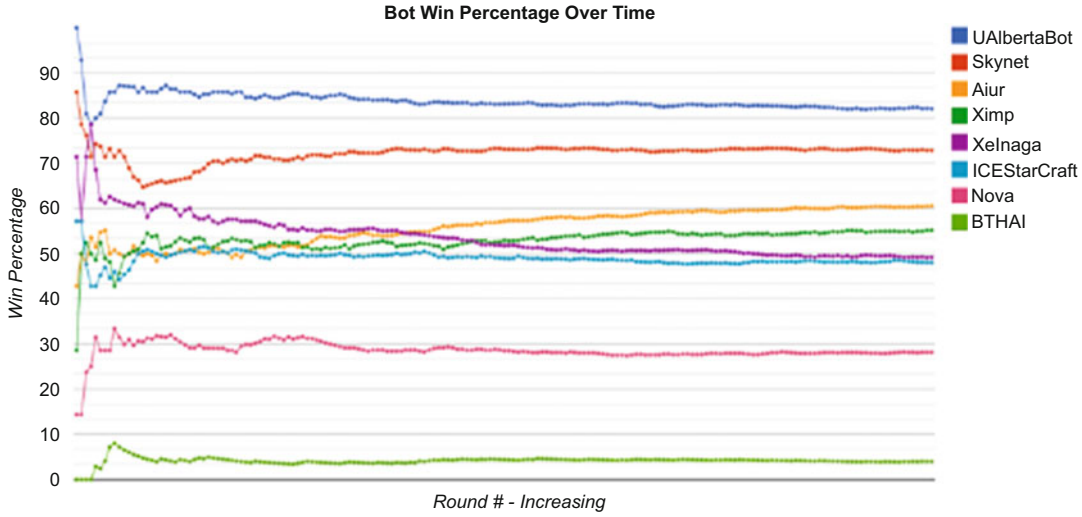
StarCraft Bots and Competitions, Fig. 2 Evolution of the win percentage of each bot participating in the AIIDE 2012 competition

StarCraft Bots and Competitions, Table 4 Results of the five best bots of the AIIDE 2013 competition

Rank	Bot	Win %
1	UAlbertaBot	84.49
2	Skynet	72.77
3	AIUR	58.51
4	Ximp	56.57
5	ICEStarCraft	48.53

had several strategies which it could implement, most starting with an early bunker defense and transitioning into attacking once a set of heuristics conditions had been met. ICEBot's source code was originally based on AIUR's modular design and changed to play the Terran race. In a close second place finish was Ximp – which had fixed the crashes and logic errors which had plagued it the year before. Ximp implemented a solid forge-first fast expansion strategy which transitioned into late-game carrier play. By building a large amount of early photon cannons in its expansion, Ximp was easily able to stop most of the early rushing bots, holding them off until its carriers cleaned up in the late game. Third place was taken by LetaBot, a new Terran bot whose source code was written on top of the 2012 version of UAlbertaBot and changed to play the Terran race. LetaBot implemented a number of strategies including a "cheesy" but strong bunker rush strategy which killed many bots very quickly, as well as a Wraith (mid-game flying unit) strategy.

AIIDE 2015. The 2015 AIIDE competition was the largest competition to date hosted by a conference, with 23 total bots competing. The competition environment was also changed so that the tournament was now run on virtual machines instead of physical machines. Doing this enabled the tournament to run for a full 2 weeks instead of the normal 1 week, resulting in a total of 20788 games being played – 90 full round robins between each bot pairing. 2015 saw the most even distribution of race selection ever in a StarCraft AI competition, with five new Zerg submissions along with seven Protoss bots and nine Terran bots. The first ever Random race entry was also submitted as UAlbertaBot had been updated to play all three of the available races. When playing Random race, StarCraft randomly assigns one of Protoss, Terran, or Zerg after the game has started, with your opponent not knowing which race you are until they have scouted you on the map. This provides a significant advantage as the enemy's initial build order must now have a period of uncertainty during which is has to guess what race it is playing against.



StarCraft Bots and Competitions, Fig. 3 Evolution of the win percentage of each bot participating in the AIIDE 2013 competition

StarCraft Bots and Competitions, Table 5 Results of the five best bots of the AIIDE 2014 competition

Rank	Bot	Win %
1	ICEBot	85.86
2	Ximp	84.64
3	LetaBot	82.09
4	AIUR	70.94
5	Skynet	68.74

StarCraft Bots and Competitions, Table 6 Results of the five best bots of the AIIDE 2015 competition

Rank	Bot	Win %
1	Tscmoo	88.52
2	ZZZKbot	87.84
3	Overkill	80.69
4	UAlbertaBot	80.20
5	AIUR	73.02

The results of the 2015 competition were extremely close, with first/second place as well as third/fourth place being separated by less than 1 % win rate (Table 6). First place was won by tscmoo, a new Zerg bot which played nearly a dozen different strategies, learning which one to choose over time via the file I/O system. In a close second place was ZZZKbot, which implement a 4-pool Zergling rush strategy every game. Despite the relatively simple strategy, most bots did not have proper defense capabilities and lost in very short games. In third place was Overkill, another Zerg bot which had several different strategies including mutalisks and hydralisks, which learned over time as well. In a close fourth place was UAlbertaBot, which played Random and implemented three main rushing strategies – one for each race. An interesting result from this tournament was that despite UAlbertaBot coming fourth place, it finished with a winning rate greater than 50 % versus each other bot. AIUR came in fifth place and was a clear demonstration of how learning over time can dramatically improve results in a tournament, going from 63 % win rate early in the competition to a final win rate of over 73 %.

CIG

An initial attempt to run a StarCraft tournament at the Computational Intelligence in Games conference (CIG 2010) suffered from technical problems. These mainly stemmed from the desire to use evolved, largely untested maps which initially looked interesting but made the submitted bots and the Brood War Terrain Analyzer (BWTA) provided with the BWAPI interface crash so

frequently that it would have been unjustifiable to announce a winner.

CIG 2011. At CIG 2011, the tournament was therefore run with a (secret) selection of maps used in league play, which can be regarded as the most important difference to the AIIDE tournament that employed a known list of maps. The competition was organized by Tobias Mahlmann and Mike Preuss and attracted ten bots. In addition to the ones discussed in previous sections (UAlbertaBot, Skynet, AIUR, Nova, BroodwarBotQ, BTHAI), the set also contained LSAI, Xelnaga, Protoss Beast Jelly, and EvoBot; these are shortly described in the following:

LSAI (Zerg) utilizes a heavily modified BWSAL (https://code.google.com/p/bwsal/) to divide management of the units to different modules that communicate via a centralized information module. It works using a simple reactive strategy to try and survive early-game attacks and macro up to a larger attack force and maintain map control.

Xelnaga (Protoss) is a modification of the AIUR bot that chooses the dark templar opening in order to destroy the enemy base before defenses against invisible units are available.

Protoss Beast Jelly (Protoss) always goes for a 5-gate Zealot rush, supported by an effective harvesting strategy named power-mining (two probes are assigned to every mineral patch, thereby needing 18 probes for 100 % saturation in a normal map, prior to expanding). Gas is not mined as it is not needed for constructing Zealots.

EvoBot (Terran) employs an evolutionary algorithm for obtaining rational unit combinations and influences map techniques for deciding the strategic locations. Note that this bot was submitted in a very early version, with many of its designed features not yet fully ready.

First Round. As the CIG competition games were executed manually due to a lack of available software (the AIIDE program was not yet available at that time), the organizers separated the ten entries into two brackets. In each bracket of five bots, a round-robin tournament was held with ten repetitions per pairing, resulting in 40 games per bot. The five maps chosen for the first round were selected from the pool of well-known league play maps found on the Internet: *(2) MatchPoint 1.3*, *(4) Fighting Spirit 1.3*, *iCCup Destination 1.1*, *iCCup Gaia*, and *iCCup Great Barrier Reef*. Each bot pairing played on every map twice, with switched starting positions.

The two top bots of every bracket qualified for the final round. Table 7 summarizes the results. Note that as BroodwarBotQ and BTHAI have the same number of wins, their direct encounter was

StarCraft Bots and Competitions, Table 7 Results of the first round at CIG 2011, held in two brackets. Qualified for the final round: UAlbertaBot and Skynet (from A) and Xelnaga and BroodwarBotQ (from B, the latter by comparing direct encounters with BTHAI of which 6:4 were won)

Rank	Crashes	Games	Bot	Win %
Bracket A				
A1	0	40	UAlbertaBot	82.5
A2	1	40	Skynet	77.5
A3	2	40	AIUR	60.0
A4	1	40	Nova	20.0
A5	0	40	LSAI	10.0
Bracket B				
B1	12	40	Xelnaga	62.5
B2	3	40	BroodwarBotQ	57.5
B3	0	40	BTHAI	57.5
B4	17	40	Protoss Beast Jelly	42.5
B5	0	40	EvoBot	30.0

evaluated which accounted 6:4 for the BroodwarBotQ. The bots going into the final were thus UAlbertaBot, Skynet (from bracket A) and Xelnaga and BroodwarBotQ (from bracket B). All qualified bots play the Protoss faction. Most bots proved fairly stable; only Xelnaga and Protoss Beast Jelly crashed relatively often (each in more than a quarter of the games). Crashing of course resulted in an instant win for the other bot. In some cases, neither bot was able to finish the other off completely, so that they went into a passive state. Such games were manually ended after around 15 min, and victory was assigned to the bot that had obtained more points as indicated on the end game screen.

Final Round. The final round was played in a similar mode as each of the first round brackets, using another set of five previously unknown maps: *iCCup lost temple 2.4*, *iCCup rush hour 3.1*, *iCCup swordinthemoon 2.1*, *iCCup yellow 1.1*, and *La_Mancha 1.1*. Letting each pairing play on each map twice again with switching starting positions resulted in 30 games per bot. The final results are displayed in Table 8, indicating Skynet as winner and UAlbertaBot as runner-up, being almost equally strong, and the two other bots as clearly inferior. The competition setup, documentation, and results can be found in the 2011 competition web page (http://ls11-www.cs.tu-dortmund.de/rts-competition/StarCraft-cig2011).

CIG 2012. For CIG 2012, the AIIDE tournament software was employed, leading to a total of 4050 games played in 90 rounds of round robin. As six different maps were used, this means that each bot played every other on every map 15 times. As in the AIIDE competition, writing to and reading from a bot specific directory was enabled, however, due to technical reasons, this feature was constrained to the computer (of 6) the game was actually run on. We can therefore assume that this feature was of minor use for the CIG competition. The only other difference to the AIIDE competition was that the used maps were not made available to the competitors in advance.

These maps came in two flavors, namely, three three-player maps: *Athena-II*, *Neo Moon Glaive*, and *Tears of the Moon*, and three six-player maps: *Legacy*, *River of Light*, and *The Huntress 1.1*. We shall note that some bots consistently crashed on one of the originally considered maps which has thus been replaced. This is surprising as all maps are well-known league play maps or have been provided with the StarCraft Brood War distribution itself. Setup, replays, and results for the CIG 2012 competition can be found here (http://ls11-www.cs.tu-dortmund.de/rts-competition/StarCraft-cig2012).

The overall results are displayed in Table 9 and the win rate evolution over time in Fig. 4. These are quite consistent with the results of the AIIDE 2012 competition, so that we can conclude that the best bots are not very dependent on knowing the maps beforehand. However, the bot versus bot win rates as displayed in Fig. 5 show some interesting trends. On the maps with more possible start points, some bots do better than others, namely, SCAIL, Adjutant, Nova, and UAlbertaBot, the latter probably due to its very efficient scouting routine. Some bots however suffer from the increased uncertainty about the enemies' position, namely, Xelnaga and BroodwarBotQ.

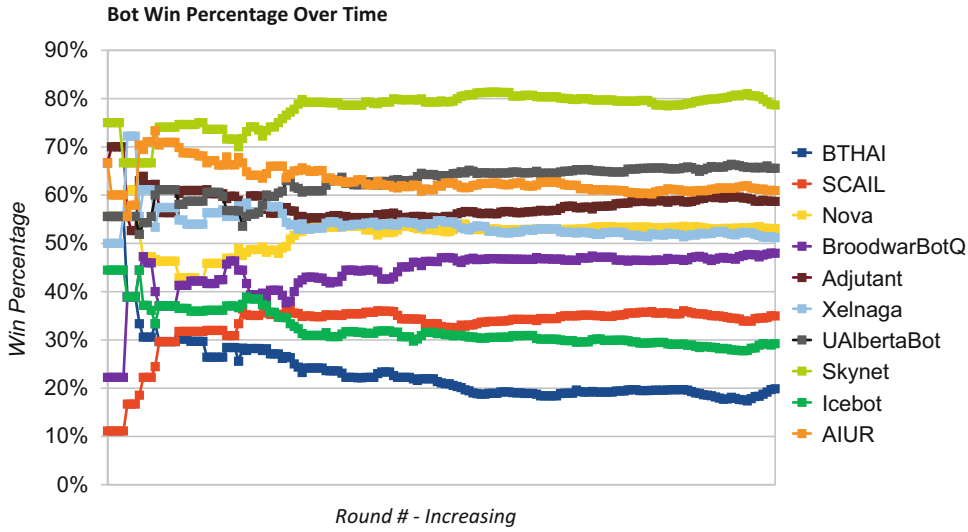
As already observed before in the previously described competitions, there are also bots who consistently beat top ranked bots but have severe problems against lower ranked bots. For example, Xelnaga is especially strong against Skynet on the

StarCraft Bots and Competitions, Table 8 Results of the CIG 2011 competition

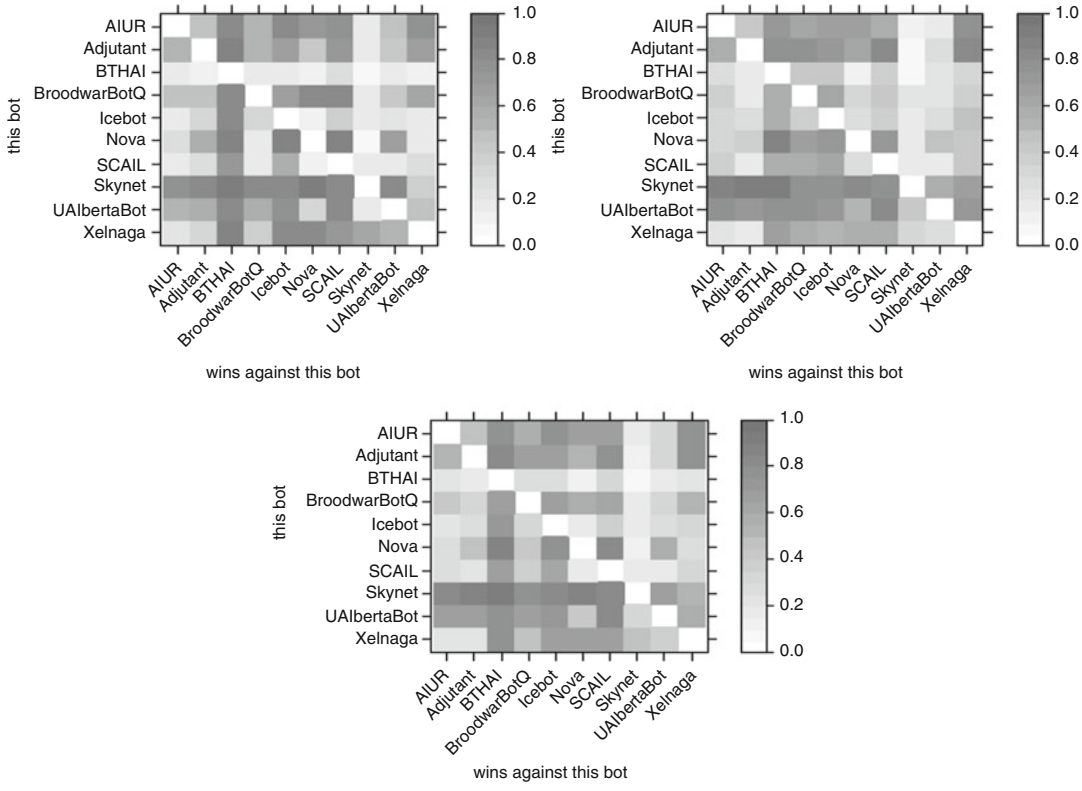
Rank	Crashes	Games	Bot	Win %
1	0	30	Skynet	86.7
2	0	30	UAlbertaBot	73.3
3	3	30	Xelnaga	36.7
4	2	30	BroodwarBotQ	3.3

StarCraft Bots and Competitions, Table 9 Results of the CIG 2012 competition

Rank	Bot	Win %
1	Skynet	78.3
2	UAlbertaBot	65.2
3	AIUR	60.4
4	Adjutant	58.6
5	Nova	52.4



StarCraft Bots and Competitions, Fig. 4 Evolution of the win percentage of each bot participating in the CIG 2012 competition



StarCraft Bots and Competitions, Fig. 5 Win percentages of CIG 2012 competition, from *left* to *right*: three-player maps only, six-player maps only, all maps. Read from line to column, bot in row wins given fraction of games against bot in column. For some bots, we find interesting differences, e.g., Xelnaga gets worse on six-player maps and UAlbertaBot gets better. Only Xelnaga can reliably beat Skynet, but only on three-player maps

three-player maps (about 70 % wins). Reviewing the replays led to the assumption that Xelnaga usually tries to attack Skynet's probes with a dark templar strategy and often succeeds. Nova does very well against the UAlbertaBot, and the replays show that it sometimes succeeds to lure the probes into its own base, where they get killed, leading to severe resource problems. However, we cannot tell how often this happens as this would require to review every single replay between the two bots. Summarizing, most bots seem to have improved, which becomes clear if the nearly unchanged BTHAI bot is taken as a baseline. In 2011, it won more than half of its qualifying games; in 2012 it came out last with around 20 % wins. However, designing a bot in order to beat a top bot (as for Xelnaga with Skynet) leads to a very restricted strategy that often leads to failure if playing against different bots. Note that in the direct encounter between Xelnaga and AIUR, its ancestor, Xelnaga, looses consistently.

Nevertheless, from the observations we made during the tournament, we can draw the conclusion that the available bots are still very constrained. No bot in the competition played the Zerg race, which is surprising as the AIIDE 2010 winner (Overmind) did so. Presumably, implementing a good Zerg strategy is more demanding than implementing one for the Protoss or Terran races. Many bots consistently crashed when playing against a random race built-in bot for testing and also did so when the map size was changed from 128 × 128 to any other. Furthermore, every single bot sometimes failed to finish off an already beaten opponent, such that the game had to be stopped after a previously determined maximum time. It also seems that most of the current bots are not very good at adapting their strategy to the one of their opponent during a game or at least (via the read/write procedure of game information) within a series of games.

CIG 2013. The CIG 2013 competition was once again organized by Mike Preuss (TU Dortmund) and Tobias Mahlmann (ITU Copenhagen), adding Antonio Mora García from the Universidad de Granada as third team member. Whereas the rules and even the participants to this competition were almost identical to the AIIDE 2013 competition setup, several technical changes were made in comparison to 2012 (http://ls11-www.cs.tu-dortmund.de/rts-competition/StarCraft-cig2013). A new competition software was implemented by Tobias but not completely finished in time, so that the read/write function that enables learning between games had to be disabled again. This is probably the most important difference to the AIIDE competition; however, as the result provided in Table 10 shows, the effect is limited. Due to the late availability of the competition software, only 32 rounds of random robin were played, making 896 games altogether and 224 games by each of the eight submitted bots.

StarCraft Bots and Competitions, Table 10 Results of the CIG 2013 competition

Rank	Bot	Win %
1	Skynet	91.1
2	UAlbertaBot	67.4
3	AIUR	54.9
4	Xelnaga	53.6
5	Adjutant	42.4

As the map set has also been changed to the ten standard maps used by the AIIDE competition (without letting the competitors know about this in advance as usual for the CIG competitions), the competitions were otherwise very similar. We presume that disabling the learning was a disadvantage for the UAlbertaBot who won the AIIDE competition and was only runner-up to the Skynet bot here. The third place went to AIUR as in 2012, followed by Xelnaga and Adjutant. A direct comparison to the results of CIG 2012 (Table 9) shows that bot evolution between these two competitions was obviously limited. It also shows that some bots as the UAlbertaBot make good use of online learning, whereas others, as Skynet, do not profit from it that much.

CIG 2014. The CIG 2014 competition was organized by Kyung-Joong Kim, Ho-Chul Cho, and In-Seok Oh of Sejong University. For 2014, the CIG competition used a total of 20 different maps which were unknown to the competitors before the competition started, which was by far the most maps ever used in a StarCraft AI competition and presented a challenge to many of the bots who entered. A total of 4680 games were

StarCraft Bots and Competitions, Table 11 Results of the CIG 2014 competition

Rank	Bot	Win %
1	ICEBot	83.1
2	Ximp	78.1
3	LetaBot	68.5
4	AIUR	66.1
5	UAlbertaBot	60.0

StarCraft Bots and Competitions, Table 12 Results of the CIG 2015 competition

Rank	Bot	Win %
1	ZZZBot	81.03
2	tscmoo-Z	73.59
3	Overkill	62.05
4	LetaBot	61.54
5	Ximp	60.26

played which meant that each bot played each other bot 60 times or three times per map. The CIG 2014 competition was held just a few weeks before the AIIDE 2014 competition and so many of the entrants to the competition were identical, and the results definitely showed this. The top four bots were all the same as the 2014 AIIDE competition with ICEBot coming first, Ximp in second, LetaBot in third, and AIUR in fourth place (Table 11). For descriptions of these bots, please refer to the AIIDE 2014 competition description as none of the top-finishing bots had any significant changes made.

CIG 2015. There were some significant rule changes to the CIG 2015 competition, which was once organized by members from Sejong University. The most significant rule change was that entrants no longer had to be open-source, in an attempt to attract more competitors who may not want to open-source their bots. The second rule change was that a single competitor could submit multiple entries to the competition – which caused some controversy among registrants since this introduces the possibility of collusion between entries. Thankfully no such collusion was detected during the competition. The 2015 competition was also not run quite as long as previous competitions with only 2730 games being played in total, or 30 between each bot pairing, six between each bot on each of the five chosen maps. There were several new Zerg entries to the CIG 2015 competition which ended up finishing in the top three positions, with results very similar to those of the AIIDE 2015 competition. ZZZBot took first place, tscmoo-Z (a Zerg bot written by tscmoo) came second, and Overkill came third (Table 12). For descriptions of these bots and their strategies used, please refer to the AIIDE 2015 competition section as the strategies remained largely unchanged between the CIG and AIIDE competitions.

SSCAIT

The Student StarCraft AI Tournament (http://sscaitournament.com/) (SSCAIT) started in 2011 at Comenius University in Bratislava, Slovakia, and has been well known for being the StarCraft AI competition with the highest number of total participants. Started as a part of a course in artificial intelligence at Comenius University, initial SSCAIT seasons included several dozen student submissions from this course in addition to submissions from across the globe. There are three fundamental differences between SSCAIT and the remaining two conferences:

1. SSCAIT is an online-only event. Unlike AIIDE or CIG, it is not colocated with a scientific conference or any other real-world event.
2. There are two phases of SSCAIT each year: a *competitive* phase, lasting for up to 3 weeks, and a *sandbox* phase which runs for approximately 11 months each year. In other words, SSCAIT is live at all times with only a few short interruptions.
3. All the games are publicly *streamed live* 24 h a day. The stream uses a custom observer script (Mattsson et al. 2015) designed specifically to improve the viewer experience and creates a continuous feedback loop for the participants who can watch their bots play against the others.

SSCAIT 2011. The first SSCAIT tournament was organized by Michal Čertický as part of the

Introduction to Artificial Intelligence course at the Department of Applied Informatics, Comenius University in Bratislava, Slovakia. It was inspired by the media coverage of AIIDE StarCraft AI competition held in 2010, but over the following years, it diverged from AIIDE competition's format significantly.

The first year of SSCAIT hosted 50 participants, all of whom were students of Comenius University at the time. The participants were allowed to select any race and use all the units and technologies in complete 1 versus 1 games of StarCraft. Vast majority of the bots were implemented to execute hard-coded strategies and behavior. Participants were divided into ten groups of five people, and 16 of them advanced into a double-elimination bracket. Final match of the elimination bracket was won by R. Danielis with a 2–1 score against M. Piovarči (both playing as Zerg).

2011 was the only year when the games were not streamed live. However, the replays were published in real time and the games from the elimination bracket were recorded and uploaded to YouTube.

SSCAIT 2012–2015. In 2012, the SSCAIT became a truly international competition with 52 participants from numerous universities including UC Berkeley (USA), University of Alberta (CAN), Washington State University (USA), University of Nantes (FRA), University of Grenoble (FRA), New University of Lisbon (POT), Gdansk University of Technology (POL), Ritsumeikan University (JAP), University of Bielefeld (GER), Sofia University (BUL), Comenius University (SVK), University of Žilina (SVK), and Technical University in Košice (SVK), as well as a number of nonstudent participants.

The format of SSCAIT changed significantly in 2012. The tournament was divided into two phases:

Sandbox phase is played nonstop during the first 11 months of the year. All the games are streamed via a video-streaming service, such as Twitch.tv or Hitbox.tv. The stream is meant to attract new entrants and to help current participants improve their bots before the second phase begins. The participants can watch their bots play against randomly selected other bots. They are allowed to upload new versions of the bots via a web interface at any time during this phase. The sandbox phase has no winners. However, the bots may use this long phase to collect useful data about their opponent's behavior.

Competitive phase is played for up to 3 weeks (depending on the number of participants) at the end of the year. New bot versions cannot be uploaded during this phase and the matches are not scheduled randomly any more. This phase has two divisions with different rules:

- *Student division*: Only the bots created by a single participant, who is currently a student, are considered "student" bots. Other bots are tagged as "mixed division" bots. Each student bot plays a single game against every other bot and collects points for the wins. Three student participants with the highest score are considered winners and receive certificates of achievement (and in years 2012 and 2013 also financial prizes collected via crowdfunding campaigns). Ties are broken using the results of the mutual game and (if necessary) additional games are scheduled. The student division was created so that the students stand a chance of winning the certificates in the presence of more experienced, nonstudent participants and team-created entries.
- *Mixed division*: Eight or sixteen bots with the highest win rate among all the participants (including student and nonstudent entries) are selected for the additional "mixed division" elimination bracket. This part of the tournament is typically recorded with a commentary and uploaded to YouTube, concluding each SSCAIT season since 2012.

The results of SSCAIT seasons 2012–2014 are provided in Tables 13, 14, and 15. At the time of writing this, the SSCAIT 2015 is still in a sandbox phase. 45 bots have registered for the competitive phase so far, including two bots playing as "Random" race. The season will be concluded by an elimination bracket featuring 16 bots in 2015.

Student division		Mixed division	
Rank	Bot	Rank	Bot
1	Ximp	1	Krasi0
2	WOPR	2	ICEBot
3	UAlbertaBot		

StarCraft Bots and Competitions, Table 15 Ranking of the best bots of the SSCAIT 2014 competition (42 participants). The student division winner was determined by means of 861 round-robin games

Student division		Mixed division	
Rank	Bot	Rank	Bot
1	LetaBot	1	LetaBot
2	WOPR	2	Ximp
3	UAlbertaBot		

From a technical perspective, the tournament was run manually in 2011 and by a collection of custom automated scripts in 2012. Since the second half of 2013, SSCAIT has been using the automated tournament managing software developed at the University of Alberta, which was modified to suit the needs of SSCAIT format and technical environment. In contrast to AIIDE and CIG competitions, there is only one game running in SSCAIT at any given time, so that each game can be streamed live (approximately 150 games are played every day). The live stream makes use of a custom-made observer script by Mattsson et al. (2015) which implements a smooth, prioritized camera movement during the game and third-party libraries that allow the game to be displayed in high-definition screen resolution.

Thanks to the tournament managing software, the game rules and I/O procedures have been synchronized with AIIDE and CIG competitions, so the participants are able to submit the same version of their bot to all three of them. In addition to bots written in C++, SSCAIT supports bots using Java interfaces to BWAPI: BWMirror and JNIBWAPI.

Conclusions

Competitions have historically been an important drive in artificial intelligence, with challenge tasks such as *Chess*, *Go*, and autonomous vehicle driving, among others having resulted in many algorithmic and theoretical breakthroughs. For that reason, we believe RTS AI competitions are playing and will continue to play an important role in the field by both motivating new research and also being an incentive to attract new students and researchers to work on some of the key open challenges of RTS AI.

This chapter has provided a summary of the results of the most three most important StarCraft AI competitions, organized during the past 6 years, as well as a summary of the architectures used by some of the bots that regularly participate in these competitions. Moreover, as evidenced by the poor results that the top bots in these competitions achieve when playing against good human players, a significant amount of open questions remain about how to design AI systems that can handle real-time adversarial domains such as StarCraft. Hopefully, these competitions can play an important role in motivating research programs that can ultimately answer these questions.

STEM Learning Through Video Games

Jaci Lee Lederman
Vincennes University, Vincennes, IN, USA

Synonyms

STEM; Video games

Definitions

STEM	Science, Technology, Engineering, and Mathematics – a term used to group together these academic disciplines when addressing education policy and curriculum design in schools.
Video Game	A game played by electronically manipulating images produced by a computer program on a display screen of a computer, smartphone, arcade machine, or other devices.
Maslow's Hierarchy of Needs	A theory in psychology proposed by Abraham Maslow to describe the pattern that human motivations generally move through "physiological," "safety," "belonging and love," "esteem," "self-actualization," and "self-transcendence."

Introduction

Those not familiar with the video gaming industry are often quick to assume that video games do not contribute to learning. This fallacy is understandable when we take into consideration the misconceptions that are present. For example, it

is true that a name can lead to stereotyping. Instantly, some people assume that the word "game" in "video game" makes the activity of gaming completely leisure with minimal learning. Unfortunately, those that are inclined to think this way might have missed out on the fun aspect of learning by doing. Additionally, video games take on a bad connotation because many parents blame video games for their child's screen time addiction. Like all good things, video games can be overused and created with content that is not socially acceptable. The same is true for books. As educators we must help inform the public on how the good can outweigh the bad when it comes to video games (How Video Games 2012).

STEM Learning Through Video Games

Video games allow players to learn many different concepts through engaging activities. The laminated cardboard cutouts used in the 1990s classroom were colorful and tactful at the time, but today's students have the Internet and desire to learn in a much more dynamic way. The education and learning process over most recent years has evolved from the classroom having one or two computers with games on CD-ROMS to every student having a Chromebook and access to numerous games on the Internet. Even though this evolution has happened over several years, it seems like the transition happened when some of us were not looking. We step back and wonder how learning occurs by playing Oregon Trail. Laughable is that learning did occur even in the 1980s by playing Oregon Trail, and the games that exist today far exceed anything that was for purchase along the journey to Oregon. This is what brings us to STEM learning. STEM, which stands for Science, Technology, Engineering, and Math, is a topic of interest for school systems and educators across the globe. The STEM movement encourages educators to introduce and focus on the STEM areas to better prepare our students for higher wage jobs requiring skills in the science, technology, engineering, and math professions. The serious need for people to work in these areas has made STEM a priority of focus.

As educators and employers, we have to look at our next generation of STEM learners to understand how they learn and why they learn. Careful consideration must be given to the resources that the next generation of STEM professionals have access to and are willing to use. Because video games are a part of most K-12 learning environment in the classroom, it makes sense that video games be used as a tool to teach STEM. Students are comfortable with playing video games and are accustomed to the challenge of making it to the next level in a video game.

How video games teach STEM really is not a secret or mystery. In actuality it is easier than taking a student to a library and giving them a book to read. Video games accessible through the Internet allow educators and employers to meet students where they already are – online gaming. The skills needed to play a video game are instilled in children from a young age, eliminating training and apprehensiveness. Students get engaged in video games that create a learning environment that is fun, challenging, and comfortable. STEM learning through video games might not allow students to reach the top of Maslow's hierarchy of needs at first, but the safety, belonging, and esteem can be achieved. To meet the demand for STEM professionals in the workforce, video games will be key to exposing larger amounts of students to the possibilities of a career in STEM much quicker than reading a book or taking a high school or college course. A young girl can feel safe to try out coding, by playing a video game on a website like code.org. A college student not confident in their math skills can become better prepared for calculus by taking game-based calculus course like the one at Texas A&M (Zarling 2018). Students ages 8–15 can play in Whyville and learn the science behind saving a coral reef (Rik on Mon 2009). In 2011, gamers playing a puzzle game that simulated protein folding found the solution to an enzyme in 3 weeks that stumped scientists for 14 years (Coren 2011).

In summary, the rationale behind teaching STEM through video games is simplistically

complicated. We have the widely accepted technology readily available for use. Numerous video games all designed with STEM in mind exist for students to take advantage of. Educators, governments, and employers alike are working together to create STEM learning. The next complex challenge is to make sure we are using these tools to help our students find a pathway from the video game to higher education to the workforce.

Immersive storytelling

Definition

Storytelling in virtual reality (VR) is the use of a narrative form to structure an immersive experience in a virtual environment as a means to engage the audience in a more sustained, active, and meaningful way beyond the initial captivation afforded by technological novelty and surround spectacle. It recruits storytelling's unique abilities to combine tangible and intangible information, and to capture context and tacit knowledge, in order to amplify presence and enhance the digital simulation's impact.

Introduction

Storytelling in VR is increasingly being employed in various fields, including journalism, the healthcare sector, cultural heritage and museology, education and training, advertising, and gaming industries (Bosworth and Sarah 2019; Papagiannakis et al. 2018). While frequently utilized in a documentary, promotional, or modeling capacity (e.g., data visualization), storytelling in VR is particularly effective when compared to conventional media in rousing users' empathy and willingness to engage with unfamiliar, challenging, or fictional worlds (Bosworth and Sarah 2019; Bucher 2018), owing to the medium's unprecedented access and embodiment potential.

In contrast to traditional oral and written storytelling primarily aimed at transmission (i.e., education, cultural preservation, and/or the instilling of moral values by means of entertainment), storytelling in VR is further oriented towards generating user agency through interaction (Riggs 2019; Arnold 2008), embodiment (Matamala-Gomez 2019), presence (Sanchez-Vives and Slater 2005), and simulation (Bertrand et al. 2019). Insofar as interactive modalities conflict with classical, pre-scripted, authored storytelling paradigms (Pausch et al. 1996), giving rise to a narrative paradox (Riggs 2019), storytelling in VR remains a nascent form that still requires further experimentation with a view to developing new storytelling models and concepts adequately tailored to the medium.

Programming Narrative Structures in VR

Programming storytelling in VR currently assumes a variety of dramatic structures ranging from predetermined linear arcs to branching narratives with diverging plotlines and/or alternative endings (Pausch et al. 1996), to highly complex rhizomatic maps of events (i.e., emergent rule-based models) that trigger one another based on user interaction (Riggs 2019; Spierling 2007) – though it has been suggested that the decisive success of the latter may yet require considerable advances at the intersection of AI and narratology (Bucher 2018). Beyond anchored 360-degree footage providing static immersive experiences, interactive functionality and navigation are generally created through game engines, combining 3D world–building capabilities with a user interface (Riggs 2019).

Irrespective of their pre-scripted or emergent nature, narrative structures in VR generally rely on classical Aristotelean elements of storytelling: archetypal characters motivated by internal and external goals with universal resonance driving a plot (series of events) constructed around conflict and resolution (Riggs 2019; Bucher 2018). They are invariably situated in a specific cultural context (Quesenbery and Brooks 2010) designed to reinforce narrative meaning and coherence by means of environmental storytelling techniques (e.g., color, lighting, and costume) to ensure a purposeful and motivated mise-en-scene (Bucher 2018; Arnold 2008). A number of VR experiences continue to be crafted around the traditional three-act structure, as well as Joseph Campbell's conception of the hero's journey (Riggs 2019; Bucher 2018). Other external sources of reference for storytelling in VR include: open-ended literary genres such as create-your-own-adventure books, immersive theater, experimental art installations, and theme park attractions (Riggs 2019; Bucher 2018; Pausch et al. 1996).

Audience Engagement

One of the main advantages of using storytelling in VR is that notwithstanding individual subjective reception owing to different cultural backgrounds, values, beliefs, and memories, simple narrative cues can provide fairly consistent user interpretations (Jerald 2016). Additionally, VR's prime affordances, i.e., presence (the feeling of "being there" in the virtual environment) and embodiment (e.g., the sense of body-ownership for a virtual body, even if radically different from one's own), result in mental constructions composed of perceptions and ideas that are different in kind from other types of knowledge, and were never before available with previous forms of interactive storytelling.

In contrast to traditional storytelling techniques, VR's shift from a frame (i.e., screen or theatrical fourth wall) to an environment requires different narrative cues and prompts, such as spatialized auditory effects (Bosworth and Sarah 2019), in order to guide the users' focus and direct their shifting center of attention within the immersive experience (Pausch et al. 1996). Rhizomatic storytelling structures further necessitate the introduction of pre-scripted plot points and bottlenecks to ensure that all emergent narratives are coherent and comprehensive, unfolding in a logical order so as to provide a dynamic but still unified experience (i.e., without plot holes, dissonance, or confusion) that is responsive and personalized to individual users (Riggs 2019; Bucher 2018). A coherent sequence lacking adequate well-timed dramatic tension will fail to sustain attention and interest, while an incoherent or nonsensical narrative arc (e.g., conflict without resolution) will lead to frustration, boredom, and disengagement (Riggs 2019).

As with any VR experience, sustained credibility is key and poses additional conditions distinct to narrative integrity. Beyond the believability and relatability of the environment, objects, characters, and avatars (Arnold 2008; Pausch et al. 1996), effective interactive storytelling in VR further requires that experiences in the virtual world correspond to social expectations in order to avoid narrative limbo (Riggs 2019) and dissociative responses. Added consideration to scene transition is equally vital in maintaining immersion, given contemporary audiences' media-conditioned anticipation of continuity in real-time, even daily life, experiences (Bucher 2018). Narrative length and pace should also be adjusted to factor in exploration time, cognitive overload (Bosworth and Sarah 2019), and various audiences' tolerance threshold for the VR experience (Bucher 2018; Pausch et al. 1996).

Narrative Paradox and User Agency

Storytelling in VR presents a narrative paradox between predetermined structure and emergent interaction (Riggs 2019): viz. between explicit authoring and implicit creation (Spierling 2007). More scripted and authored narratives can stifle user interaction, while extensive agency can flatten, even eliminate, dramatic structure (Riggs 2019). If the absence of a frame suggests the need for new types of story-worlds built around dynamic emergent narratives evolving in response to user interaction (Riggs 2019), human's inbuilt neural propensity towards pattern processing may still advantage traditional narratives over nonlinear stories (Bucher 2018). Ultimately, successful storytelling in VR requires a balance between dramatic structure and user agency (Pausch et al. 1996).

Depending on the extent of scriptedness and interactivity, user engagement can range from static immersion: whereby the user might have a stationary position in a fixed narrative designed to elicit an increased sense of empathy vis-a-vis an unfamiliar situation; to extensive interactive, even creative control: where the user is given broad agency to determine the storyline based on personal goals and motivations (Bosworth and Sarah 2019; Riggs 2019; Bucher 2018). These different kinds of engagement programmed through different points of view, positions, and functionalities amount to different types of user agencies with diverging effects. Users might be granted protagonist status with God-like influence over the simulated environment (Riggs 2019) amenable to being manipulated at will – which can raise ethical issues related to playing out personal fantasies (Bucher 2018); or assigned the role of a supporting character or invisible observer (Bosworth and Sarah 2019; Bucher 2018), akin to an ethnographer or critic, conducive to a more critical, judgment-based mode of engagement – that is, however, circumscribed in its impact on the virtual environment.

In either respect, aside from interactive features, active storytelling approaches that leave deliberate gaps in thematic or narrative detail to be completed by the user present another effective means of compelling audience involvement through imaginative projection (Bucher 2018). Such parcity in detail can effectively serve to condense information and simultaneously elicit personal investment and connection to content

through mental imagery (Bertrand et al. 2019), sparking understanding and innovation, and even amounting to ownership and coauthorship (Quesenbery and Brooks 2010).

Conclusion

Given that narrative structures are fine tuned to human cognitive patterns of attention and problem-solving, storytelling in VR can contribute to greater presence and agency via embodiment and interaction, conducive to more individually meaningful experiences in simulated environments. It is an efficient means of structuring user engagement in virtual worlds for audiences that are increasingly becoming accustomed to nonhierarchical interaction, and eager for momentous and immediate experiences to offset image saturation (Bucher 2018).

Synonyms

Game development; Game strategies; Indian perspective; Purposeful game; Serious games

Definition

Serious games are those games in which the primary objective is not fun or amusement, but to learn or develop skills. Their goals may be one of many: training defensive teams in emergency situations, training for a marketing team, teaching science, or rehearsing a language. These games have the potential to create empathy for particular topics, spread awareness users about important issues, and solve problems with evolving behavior.

Introduction

Great Philosopher Plato quoted "Life must be lived as a game". Play is inherent in the human psyche. Translations of human activities into play for recreation have taken place since the evolution of mankind. From the Stone Age to Mesopotamia to Mohenjo-Daro, across civilizations, human artifacts and behavior were reflected in a style of playing that constituted a game. Games generally obey those laws that are conditioned by society. A game requires the human mind to elicit fun using its cognitive reasoning. The human mind appears to make games based on its emotions.

Game can be described as a physical or mental contest following particular rules and having players with the target of amusement or rewards (Williams 2006). Various types of fun games, such as board games or video games, follow the direction of wining or loss. Sometimes the players' minds get so engaged and involved that they get addicted to it. In today's context, games are no longer just for recreation purposes, they have also begun to be used as tools to serve behavioral changes among people. Such games have some meaningful purposes apart from fun. So, evolution has happened and given rise to games with purpose. These were named as "Serious Games" wherein players gain an understanding of real-world issues through play.

Origin of Serious Games

The origins of serious games are quite old. In 1970, Clark C. Abt coined the word "serious games" (Abt 1970) in his book and the term was later popularized by Ben Sawyer in 2002. However, considering the rich history of purposive play, these are traceable to Plato's work. In a way, serious games is a contemporary manifestation of centuries-old theories and practices. "Chaturgana," that historians claim to be the precursor of chess, was the first game to explicitly apply a militaristic metaphor to a board game developed in India in the seventh century (Shenk 2011). Chess, although it might be popularly regarded as an entertainment game, has the underlying element of strategic skill training and is therefore a form of serious games.

However, these are traceable to Plato's work in view of the rich history of purposeful play. Serious games is somehow a contemporary manifestation of theories and practices that go back centuries. "Chaturgana" was the first game to explicitly apply a militaristic metaphor to an Indian board game developed in the seventh century (Shenk 2011). Chess is a strategic training component, although it can be popularly considered as an entertainment game, and therefore constitutes a form of serious games.

Accepting this as a beginning stage, we would then be able to follow this aggressive use of games to more unmistakable advanced serious games, for example, America's Army, Phil Wilkinson discovered in his research that there are examples of pre-digital games intended to create social change and the legislative use of games for serious purposes, similar to the recorded use of games in instructive and military settings. Similarly, the Landlord's Game, which was supposed to be the precursor to Monopoly when it was founded in 1902, was intended to show the risks of capitalist approaches to land taxes and rental property (Alvarez and Djaouti 2011). Concepts dominant in the debate on contemporary serious games are also concepts reapplied from historical origins.

Various Applications

Serious games are persuasive games that enable players to obtain through play an experiential understanding of real-world issues. Numerous in this developing class of games tackle social causes. Serious games in real-world scenarios are often intended to "improve" players' knowledge, awareness, or skills. They may seem like simulations of infotainment, training, therapy, or even propaganda. These games are generally used in education, training, health, public policy, defense, and strategic communication.

Serious games were adopted in early psychoanalytical methodologies. In fact, they can be traced back to Sigmund Freud as the first case of play in a therapeutic setting. He suggested to the parent that the child watch play at home in a way that provides an insight into their mindset when treating a young phobia affected boy (Roos and Roos 2006). The use of play by Anna Freud as a means of developing child therapy relations was similar to this approach created by Freud and extended further by Madeleine Klein. Perhaps Carl Rogers' humanistic psychologist's work in the field of play therapy is of the utmost importance today for the therapeutic use of serious games (Rogers and Dorfman 1951).

Popularization

Apparently, the spectrum of serious gaming applications in the healthcare sector is very diverse. In the same way, there is a range of different players in this field, including hospitals, clinics, private practitioners, consultants, staff trainers, government, businesses, and other organizations and individual users. The popularization of gaming coincided with the technological transition from analog to digital gaming. Rosemary Garris, Robert Ahlers, and James Driskell created a thorough analysis of preexisting research into serious games to strengthen its application in education in 2002. Garris et al. (2002) have worked with the United States Section of the Naval Air Warfare Center, showing the military's continued role to advance research in serious games. They also looked at the work of existing researchers with a view to developing an illustrative and formal model for serious educational games (Garris et al. 2002). Finally, they illustrated their work as an educational game.

Serious games can be enhanced to a wide range of uses, e.g., military, governmental, educational, commercial, publicity, healthcare, etc. Serious gaming encompasses games used for purposes other than sheer entertainment, such as e-learning, game-oriented learning, and game-based interactive learning. These games allow students to experience scenarios that would otherwise be impossible due to security concerns, financial constraints, time constraints, and so on. Serious games incorporate cognitive theory with human behavioral psychology, game design, and are designed to improve the student's understanding of the intended purpose (see Fig. 1). Serious games cover all facets of education and learning well beyond teaching and rote memorization.

The Army Battlezone, designed by Atari in 1980, was the first "serious game." However, the American Army was one of the most famous and perhaps leading examples of serious games in 2002. The game highlights realism, and all weapons and cars, for example, are exact virtual replicas of the real thing. This game became very popular, as a community of four million registered players was downloaded 17,000 times in the autumn of 2004, and the number of players increased by 100,000 per month (Michael and Chen 2006) With an investment of 16 million dollars in the U.S. Army, the game has been a success to help the Army recruit 15% of its recruitment costs (Grossman 2005; Michael and Chen 2006). The game also helped to strategies and was used by active soldiers to prepare for missions with subsequent modifications and extensions (Michael and Chen 2006). Another advantage of this particular game (for the Army) is that its target audience considered it to be an important source of military information and knowledge. It is estimated that 30% of Americans between 16 and 24 years say that they have learned something from this game about the army (Grossman 2005).

Categories of Serious Games

In the same way, serious government policy games will include different types of tasks and circumstances, such as dealing with terrorist threats, outbreaks of disease, biohazards, health policy issues, urban planning, traffic management, firefighting, budget balancing, ethical training, defensive driving, and other crisis management. In order to simulate scenarios that are too risky, difficult, or costly to handle, that are hazardous and train havoc, most of the simulations will be made for different types of emergencies, for example, firemen, policemen, or medical personnel. Similarly, serious education games can advance the improvement of a scope of abilities: strategic thinking, planning, communication, teamwork, community decision-making, cooperation and negotiation (Kirriemuir and McFarlane 2004). With the renewed interest in serious games, game creators have shifted from 'mugging and repeating' learning paradigms to situational and experiential learning where people are active in making tangible objects in the real world.

There are majorly five categories of serious games classified by Alvarez and Michaud (2008) as represented in Fig. 2. The games that raise awareness of issues help to train motor functions, develop social skills, develop ability to respond to sudden onset crises, and improve imagination. It helps grow entrepreneurial potential, build human capital and workforce, and enhance organizational management. Today's corporate training market is a large industry in which serious games are widely used. In the 1990s, computer-assisted training was introduced to digital PC companies, first with CD-ROMs, and later on the Internet. While computer-aided training allowed firms to reduce training personnel, special equipment, places, and so on costs for training, there were not significant differences in learning and interaction compared with previous training courses (Michael and Chen 2006). As new technology and media are available, they are adopted for corporate training and for several reasons. Interest in major games and simulations is now growing. The number of employees familiar with video games is increasing and their interest in

Strategies for Design and Development of Serious Games: Indian Perspective, Fig. 2 Categories of serious games

interactive serious games is quickly and effectively captured.

Corporate serious games may include a variety of subjects, some common to various corporations, while others are unique to the needs of a company itself. These games address skills that companies need to train their workers in, such as interpersonal skills like teamwork, job-specific skills of software/hardware knowledge – organizational skills including managing resources and energy, communication skills, and planning skills.

Serious games provide a paradigm shift in training, changing the position of the trainee from passive to active, from simply supplying materials to facilitating the trainer's role. These games allow the learner to get feedback on behavioral outcomes using assessment methodologies that can be both quantitative and qualitative. Serious games applications are becoming more popular and there are various kinds available nowadays. Healthcare is the application field of serious games that will expand mostly in the coming years according to Ben Sawyer, co-founder of the Serious Games Initiative. Dance Dance Revolution game (DeMaria 2006) may serve as an example of serious games and input tools that encourage healthy behavior, such as a stationary bike. By incorporating physical activities to the entertaining elements of video games, or vice versa, physical activities are more appealing.

Indian Folklore and Serious Games

Recently in India, many have explored the domain of serious games to enhance efficiency corporate workflow and trainings and been developed independently. Like, "Acting Kindly" is a kind of serious games developed in India to make kindness fun. It is a perfect game for parents to play with their children, organizations to encourage team building, or for friends to have a fun time while making the world a better place. It encourages people playing can run along doing acts of kindness in public.

India is currently experiencing a transitional period as it embarks on a grand journey towards growth. This is a very interesting and probably the most important phase the country is witnessing. Modern ideas are being challenged today by old ideas and institutions. Innovative solutions are being provided to both old and new issues. However, there are few major issues and challenges which need to be dealt effectively for significant progress.

Content, creativity and common sense can be strategically combined to design novel game concepts that make societal impact, while being fun to play. Games can be designed to address digital inclusion, women safety, traffic behaviors, clean India – things that matter in day-to-day civic life in the Indian context (see Fig. 3).

Strategies for Design and Development of Serious Games: Indian Perspective, Fig. 3 "Rani Laxmi Bai" India's warrior queen from history could be used in RPG (role-playing game) where she would be guiding young girls for self-defense

Jataka Tales to Serious Games

The gamut of serious games could be explored in different games with purposeful meanings. Game designers could connect the dots and find solutions to current issues in India, by creating strong, original narrative games inspired by India's own indigenous stories and culture. One could revisit native subjects and see things from different perspectives, to come up with solutions to serious games that are needed to push the boundaries. One could explore Indigenous Tales (Indian Folk Tales) and apply to solve the present problems plaguing our country.

India has a huge collection of courageous ballads and epic verses safeguarded in oral convention, both in Sanskrit and the different vernacular dialects of India. There is an enormous potential in the digital serious game arena to create games that are influenced by the culture and folk tales of India. Panchatantra, for example, offers human life moral values. It is estimated that The Hitopadesa is at least many centuries old. Originally written in Sanskrit, animals were often used to represent values about how to behave in everyday life. The Jataka tales are a voluminous body of Indian native literature about Gautama Buddha's previous births. These are the stories that tell, in both human and animal form, about Buddha's previous lives (Panda 2013).

Conclusion and Future Scopes

Indigenous stories and Indian history have tremendous potential to be used in dealing with issues prevalent in India. For instance, crime like against women such as rape could be highlighted by RPG (Role- Playing Game) wherein the protagonist could be Rani Laxmi Bai (the historic brave lady figure). She could be a warrior against such crimes and teach different techniques of self-defense to young girls. The narration could be inspired by Rani Laxmi Bai in the present urban scenario (Deshpande 2008).

Likewise, to create awareness on the other socially relevant topics in India, like protection of the girl child, unplanned pregnancy, abortion of female fetus, etc., serious games could be developed having strong narration which would be truly "Indian." Serious games for tackling the present challenges in India such as water scarcity, pollution, public transportation, road safety, digital banking, etc. could have a back story inspired from Indian cultural gems like Jataka tales or Panchatantra. Such Indian heritage has strong moral values which are still very relevant in the present scenario. The solution could be built into the progression of the game. Indigenous Indian narrative could make the whole experience interesting. The purpose of such games could range from providing learning, creating awareness, solving problems to changing behaviors. Businesses, governments, NGOs, and educational

institutions are considering serious games to promote their commercial either social causes or to facilitate academic learning. The purpose of such serious games may range from providing instruction, generating knowledge, solving problems, and helping to change attitudes and behavior for betterment of mankind. These games can be used by government, educational institutes, corporates, NGO, etc. for several kinds of awareness campaigns in the public domain. Serious games are perceived not only as an entertainment source but also as an effective pedagogical tool (Shaffer et al. 2005). Simulation and other games are very useful in allowing user to experience real-world problems and improving their understanding.

As a future scope, apparent usability testing of serious games with players may be useful to investigate along with the visual aesthetic might have same effects performance (Shirole et al. 2018). Human factors/ergonomics research aids in the development of appropriate serious game attributes. These users' requirements include emotional attachment to serious games, cultural perceptions, and social value systems, all of which will provide valuable insights for game developers (Chowdhury 2020; Chowdhury et al. 2014; Goyal and Chowdhury 2021).

Further, serious games can also be combined with hypnotic voice user interfaces to enhance the player's engagement in future. Hypnosis and hypnotherapy are fascinating forms of interaction between the subject and the hypnotist, with very subtle suggestions (Ramadas and Chowdhury 2020) introduced in their research article a new type of discrete human-machine interaction called hypnotic computer interfaces. The triggers can be verbal, nonverbal (such as guttural sounds, gestures, and facial expressions), intraverbal (a combination of two or more words), or extraverbal (a combination of verbal and nonverbal). The input can come from humans and the feedback can come from the machine, or vice versa in this type of interaction.

Serious games have the potential to act as alchemists, assisting in the transformation of society. Moral lessons in folk tales assist young people in developing as healthy, mature, and responsible members of society (Dixit et al. 2017). Inspiring morals from our country's indigenous folk tales could be strategically used to promote values, thereby improving human life and society as a whole.

Stress Reduction, Relaxation, and Meditative States Using Psychophysiological Measurements Based on Biofeedback Systems via HRV and EEG

Jeffery Jonathan Joshua (ישוע) Davis[1], Robert Kozma[2] and Florian Schübeler[1]
[1]The Embassy of Peace, Whitianga, New Zealand
[2]CLION, Department Mathematical Sciences, University of Memphis, Memphis, TN, USA

Synonyms

Psychophysiological coherence and cognition of inner peace and harmony

Definitions

Electroencephalography, or **EEG**, is an electrophysiological monitoring device comprised of multiple electrodes (small, flat, metal discs with thin wires) placed on the scalp that send signals to a computer in order to noninvasively measure and record electrical activity on the scalp. **EEG** can be used in cognitive research or to diagnose conditions such as epilepsy and sleep disorders.

Heart rate variability (HRV) is a measure of the patterns prescribed by interbeat intervals of time and the functioning of the heart. **HRV** has been described as a psychophysiological biomarker to assess coherent or stressful states associated with respiration, cognition, and emotions (McCraty et al. 2009).

Psychophysiological coherence has been widely described as a state conducive to optimal cognitive performance and improved health (McCraty et al. 2009) that has also been associated to inner balance, peace, and harmony (Davis et al. 2018).

Biofeedback systems are computerized devices that provide information about the activity of physiological measures, such as heart rate variability, in order to learn how to modulate at will specific body functions to improve energy management, health, self-mastery, and general well-being. Biofeedback systems may include HRV, EEG, ECG, EMG, and respiration machines, among others.

Brain or heart computer interface refers to cybernetic systems that allow data acquisition from sensors or electrodes, which monitor brain dynamics via EEG or cardiac activity via HRV, with the possibility of online processing and data storage capacity.

Multiuser computer games are games that allow audiovisual and text exchange via personal computers, laptops, tablets, or smartphones, which facilitate online interaction between different users in different locations.

Introduction

Since ancient times humans have lived in a struggle between the fulfillment of survival needs and the achievement of inner peace. Many ancient traditions provide a body of wisdom with tools and practices to achieve such inner states. However, for the majority of people “making a living”

in the modern world, long meditation retreats or spiritual quests become a luxury that is difficult to attain. Fortunately, modern technology when combined with ancient wisdom, mainly breathing techniques, can support us to move closer toward the ideal of inner peace with very good results. Recently many users of biofeedback systems have incorporated these tools to accelerate their learning process in achieving peaceful cognitive states associated with low stress levels and cognitive clarity, with their associated mental, emotional, and physical benefits. There are different types of biofeedback systems available; however, here we focus on EEG and HRV only.

The purpose of this entry is mainly informative and emphasizes the benefits of using biofeedback systems in order to reduce and manage stress as well as to harness positive emotions, optimal cognitive performance, general well-being, and inner peace. Throughout the entry the reader is guided and referred to what the authors consider a condensed, solid body of literature to support in deepening his or her understanding on the subject. Perhaps one of the main contributions of the entry is in highlighting the need to synthesize a body of knowledge that brings together the role of brain, heart, and respiration interactions in mediating cognition associated to inner states of peace and harmony. The authors would be glad if the reader felt encouraged and inspired to conduct more research in this promising area as well as derive benefit from the use of these kinds of biofeedback systems.

Modern biofeedback systems combine the analysis of EEG data together with a very coherent, informative, and aesthetic display and are able to provide an almost instant reading, as well as keep records of the different sessions of relaxation or meditation, for example, and their associated brain dynamics. This serves the user in learning how to modulate brain states at will, by making sense of the graphical output in relationship to the subjective knowledge of one's self and one's cognitive states. With practice and attention, the user can induce at will alpha (~10 Hz) states in certain regions of the brain, and that may serve as a biomarker for, let's say, a relaxed state (Davis et al. 2017; Davis and Kozma 2018a). Such a tool can also be enhanced by a monitor of HRV, which according to many studies (McCraty and Tomasino 2004; McCraty et al. 2001, 2006; Davis et al. 2018) serves as a good indicator for psychophysiological coherence and relaxed and harmonious inner states. Most of the currently widely available biofeedback systems provide one or the other tool; however, it is expected that in the near future, biofeedback systems will integrate heart and brain measures together with others like respiration rhythms and hormonal release measures, for example.

More importantly, all these technologies, we conjecture, could be integrated to a new generation of multiuser computer games, which will challenge and support every user in virtual interactions to acquire cognitive and psychophysiological coherence skills. These computer games could also be integrated as part of the education process in acquiring social skills and the knowledge to achieve general well-being. It is important to note that these computer games could also be developed in applications for smartphones and other devices with intelligent advisors that suggest a set of activities or missions to be accomplished and monitored in real life, for example, the new application by the name "Mission Me" (Apple Inc. 2018).

Biofeedback Systems, a Means to Relaxation, Meditation, and Stress Reduction

Cognition and Brain, Heart, and Respiration Interactions

Understanding the complexities associated with the generation of peaceful inner states is a prerequisite to building reliable biofeedback systems. For example, when the synchronization and desynchronization between different oscillatory systems in the body are observed via multiple biomarker measures, we are challenged to systemically study the dynamics of the heart, the brain, and the respiratory system to name a few and, in doing so, unravel their coupling properties in

describing different cognitive states usually associated with different emotional expressions as shown in recent studies (Heck et al. 2017). It is common knowledge that emotional and mental states that are commonly associated with an "aching heart" and a "confused mind," caused by marital breakdown, for example, come together with very different bodily sensations than the experience of "nirvana" or "joy" that people experience in meditative states. Therefore, it becomes relevant to know how the heart, the brain, and the hormonal system act as coupled oscillators and then use this knowledge to learn how to modulate their dynamics at will, via the respiratory system, with rhythmic breathing techniques that may facilitate a transition from an "aching heart" into a "joyful" one and from a "confused mind" to a "clear mind" state.

The Engineering of Biofeedback Systems for Well-Being

The design of a biofeedback system is a work of engineering that may require input from many different areas of knowledge like science, art, philosophy and ancient wisdom, and most certainly the development of mathematical methodologies that involve both linear and nonlinear systems and that could possibly describe brain dynamics, for example, as a consequence of intentional action and values-based decision-making, leading to cognitive states which are associated with inner peace and harmony, involving the abovementioned oscillatory systems (Baars 2013; Freeman et al. 2000; Buzsáki 2006; Davis 2009; Schwartz et al. 2005; Kasamatsu and Hirai 1966; Austin 1999; Childre and McCraty 2001; McCraty and Tomasino 2004).

This would mean that a well-designed biofeedback system should allow the user a cybernetic interaction (human-machine interaction) with the goal and intention to achieve relaxation and inner peace by exploring different choices and making decisions that are valuable and meaningful for the user, for example, meditating before an exam or important meeting in order to improve cognitive clarity and emotional stability (McCraty 2002, 2017; McCraty and Tomasino 2004).

Brain and Heart Dynamics, Cognition, Consciousness, and General Well-Being

Some authors have developed theories and methodologies to study cognition that are intended to improve on the understanding of the brain in a holistic or systemic way, based on brain field dynamics (Kozma et al. 2012; Davis and Kozma 2012, 2013; Kozma and Freeman 2002; Pribram 2013). These methodologies based on Freeman's neurodynamics and Pribram's view of the brain are very relevant to the study of mind and consciousness, as manifested in nonlinear brain dynamics that involve large cortical regions intended to uncover how the brain allows for perception of reality and the emergence of knowledge and meaning in relation to the higher faculties of the mind (Del Cul et al. 2007; Seth et al. 2008). The reader needs to note that the mind and its workings are intimately related to the willful generation of relaxed, less stressful, and ideally peaceful states and that these kinds of theories and methodologies are instrumental in designing algorithms to analyze brain data, which ultimately can be embedded in robust biofeedback systems that allow for cognitive inner state exploration via monitoring brain activity (Davis and Kozma 2014, 2018a).

Similar theories and methodologies have also been developed for the analysis of heart rate variability signals based on a thorough understanding of the complex interaction between the two branches of the autonomic nervous system, the respiratory system, and the heart. These methodologies have also contributed to the design of biofeedback systems that support the learning process of modulating one's cognitive and emotional states (McCraty et al. 2006).

The Art of Electroencephalography (EEG) as a Qualitative Biomarker

Perception of reality is modulated by the interaction of the environment and our human body. Each time we receive sensory input or generate internal signals associated to hope for a desired goal, for example, our brain, which is a very complex system, interacts and communicates

continuously with different systems in the body, like the nervous, cardiovascular, and respiratory systems, to name a few. The body, when taken as a whole, is better comprehended in its functioning, and it is easy to realize that changes which manifest in one bodily system will affect other organs, members, or systems of the body. Intentional action requires the brain to create knowledge and meaning and that in turn provides a means for evaluating, coordinating, and controlling human behavior. Learning about our reactions and thought patterns and how to keep and nurture the constructive ones, while addressing properly the destructive and negative ones, requires self-vigilance and mastery. Meditation has been proposed as a practice to achieve such self-mastery, and Sarah Lazar among others has conducted studies in this area. The reader is directed to a comprehensive list of Lazar's publications (Lazar 2018).

Disturbances associated with stress that are received from diverse sensory input have been shown to manifest in a variety of frequency bands in brain dynamics (Freeman and Quiroga 2013; Freeman et al. 2003), while peaceful cognitive states, when self-induced via meditation, have been observed predominantly in the mid-range of brain frequencies known as the alpha band (Freeman et al. 2000; Buzsáki 2006; Davis 2009; Schwartz et al. 2005; Kasamatsu and Hirai 1966; Austin 1999). In order to benefit from the information that our brains can provide, we need tools like biofeedback systems that are integrated to EEG data acquisition and the analyses of these EEG signals.

Modern technology has allowed for EEG-based biofeedback systems that can incorporate a graphical display module of brain signals or a movie of spatiotemporal brain dynamics (Davis et al. 2015a) that help the practitioner or user to engage in visualizing brain patterns, either intermittently during or post meditation, in order to learn to change the pattern that is visualized, by changing breathing patterns or attention, for example, until the desired cognitive states are achieved. It is similar to an explorer seeking for a path to the river in the forest; once it is found, traces are left with the proper markers. In our case these markers are movies or displays of brain dynamics (Davis and Kozma 2018). A practitioner or user could learn the differences between various cognitive modalities and their associated brain dynamics and subjective experience, such as (a) closed eyes; (b) open eyes; (c) open eyes accompanied by a visual stimuli, like an intermittent flashlight; and (d) intentional meditation to generate peaceful states of being (Davis et al. 2016, 2017; Davis and Kozma 2018a).

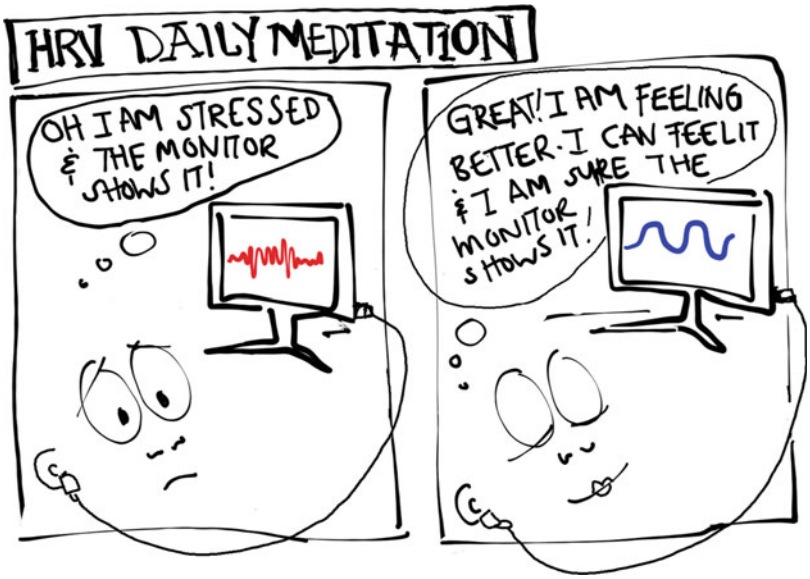
In order to quantitatively classify between modalities and cognitive states, the future of biofeedback systems will need to provide user-friendly interfaces for that purpose. In so doing, the user would be able to learn to discriminate between states with a high degree or level of certainty or significance toward a deeper understanding of the neural correlates of his or her own consciousness. In order to achieve all this, various already available studies from different fields and disciplines, such as mathematics, systems neuroscience, and engineering, among others ought to be combined (Kasabov and Capecci 2015; Davis et al. 2016; Pribram 2013; Kozma et al. 2014). The advances in biofeedback system technologies suggest a new direction to approach the exploration of questions in regard to consciousness and mental activity and how they are reflected in brain dynamics that complements ancient wisdom and philosophical thought (Davis et al. 2015).

Heart Rate Variability (HRV) as a Measure of Psychophysiological Coherence

Heart rate variability has been extensively studied to the understanding, among other things, of the effect of different emotions and their associated stress levels, usually referred to as psychophysiological coherence (McCraty and Childre 2010; McCraty et al. 2001; Childre and Cryer 2008).

There are different ways of experiencing changes in psychophysiological coherence; some are toward higher stress levels, while others are toward more coherent states with an associated significant reduction in stress levels. This can be monitored via a coherence ratio, which is an index that presumably captures the relationship between the two branches of the autonomic nervous system

Stress Reduction, Relaxation, and Meditative States Using Psychophysiological Measurements Based on Biofeedback Systems via HRV and EEG,



HRV DAILY MEDITATION
OH I AM STRESSED & THE MONITOR SHOWS IT!
GREAT! I AM FEELING BETTER. I CAN FEEL IT & I AM SURE THE MONITOR SHOWS IT!

Fig. 1 Difference in the signals between psychophysiological stressful states and coherent states mediated by meditation. (Art form courtesy of Carey Jackman at The Embassy of Peace, Whitianga, New Zealand)

(sympathetic and parasympathetic) via a Fast Fourier analysis of the HRV signal. There is extensive literature about how to calculate the coherence ratio and how to interpret it or derive other useful signals from it. The brain, heart, and respiration dynamics are essential in mediating psychophysiological coherence, and this is reflected in HRV measurements (McCraty et al. 2006) (Fig. 1).

Several technologies and diverse equipment have been developed for the monitoring of HRV, ranging from clinical and research devices like the Firstbeat monitor (Firstbeat Technologies Ltd. 2017), as well as monitors that can be used on a daily basis by the general population, which are very accessible, like the emWave Technology (HeartMath LLC 2016).

Several authors have studied the relationship between perception, awareness, spiritual experience, relaxation, and general well-being, presumably involving the coupling of the brain and heart, modulated by respiration (Kim et al. 2013; Childre and McCraty 2001). It is important to mention that there is an extensive body of ancient wisdom, philosophical ideas, and hypotheses that emphasize the role of the "heart" in "basic leadership," intentional action, and decision-making (van der Eijk 2007). Much of the advice that we find in various texts suggests different ways in how to handle the "more profound" spiritual experiences (Davis 2009). However, in this section, we focus on the application of HRV and psychophysiological monitoring technologies, which come as a means to assist every human being who is willing to find inner peace and harmony and access high coherence levels, regardless of his or her metaphysical commitments, and, in so doing, create a neutral biological bridge to the different understandings about the subject of inner peace. There are profound implications associated to the use of such devices in fostering individual and social harmony, related to deep feelings of appreciation, love, and compassion (McCraty 2002; Crivellato and Ribatti 2007).

Conclusions and Future Perspectives

Recent studies have shown that the heart is involved in the modulation of physiological states associated with emotions that can lead to stress or tranquility. Mastering desired physiological and cognitive states at will has become almost routine for practitioners of meditation and relaxation, leading to what more recently has been known as psychophysiological coherence or heart cognition (McCraty et al. 2006). We have touched on scientific knowledge applied to the understanding of how to embody peaceful states of being, which

are meaningful and valuable to the individual's decision-making process. We have also mentioned that the combination and proper application of wisdom, science, and technology may lead to individual peace and social harmony, where the ancient art of peaceful living is turned into a science of coherence (Childre and McCraty 2001; McCraty 2017).

To develop inner peace in a way that is meaningful to the individual requires the brain to derive meaning from internal as well as external events that will facilitate the creation of new deeper meanings and a broader knowledge of reality and self (Davis and Kozma 2013; Kozma and Davis 2018). We have highlighted that it remains a mystery to be solved how the brain and heart participate in the creation of trivial and deeper meanings and the fact that in recent years, science has taken an active role in the exploration of this mystery via the art of encephalography and EEG.

We have mentioned that recent technologies have been developed to measure HRV and that studies of heart coherence have flourished, almost as a form of standard language, to build a bridge between subjective experiences, associated with different paths toward inner peace, and objective measures, like the coherence ratio associated with coherent cognitive states. For all practical purposes, in the broader arena of society where secular views merge with spiritual ones, the term psychophysiological coherence refers with great clarity and in a scientific way, to an initial step to "unlock the doors" to higher cognitive meanings in the spheres of psyche, soul, and body (Childre and McCraty 2001).

The ideas presented here have the potential to advance a science that will improve the understanding of values-based decision-making and, we conjecture, will facilitate a change in perception and perhaps in paradigm, for an individual to constructively apply his or her intelligence and choose, at will and consciously, for peaceful behaviors to improve society and leave a better place and possible scenarios of peaceful living for future generations. In all certainty, a good beginning is associated with the use of brain and heart biofeedback systems for stress reduction, relaxation, and meditation.

The new generation of biofeedback systems should aim at an integration with brain and heart computer interfaces that allow the user to learn about his or her cognitive inner states, as part of computer games that are both fun and challenging, to keep the learning process interesting and alive. With the success of such an endeavor, we could aim at inspiring and motivating children, teenagers, and adults ideally from all cultures and places to keep engaged in the quest for inner peace. These games could be interactive between people from different parts of the world who challenge and support each other to develop such skills.
